HP 82184A Plotter Module

Owner's Manual

For Use With the HP-41

January 1983 Rev. B

82184-90001

Preface

This manual was written with the assumption that you have a working knowledge of the HP-41 Handheld Computer, the HP 82160A HP-IL Module, a compatible plotter, and—for those using the plotter module's bar code functions—the HP 82153A Optical Wand. For information regarding the operation of any of these units, please refer to the appropriate owner's manual.

To use the HP 82184A Plotter Module, you need to know some basic operating information, plus the operation of the module's Utility Plotting Program and/or individual plotting functions. The two main parts of this manual cover these topics as follows:

- Part I (sections 1 and 2) describes module installation, HP-41 memory and system configuration, and how to use this manual; then provides three plotting examples and a detailed description of the Utility Plotting Program.
- Part II (sections 3 through 8) describes the plotter module's individual plotting and bar code functions, as well as programs you can use to expedite bar code generation.

Appendix A describes plotter module-related error messages. Appendix B provides care, warranty, and service information. Appendix C provides annotated program listings including three programs that enhance the use of the plotter module's Utility Plotting Program, and flowcharts. Appendix D provides bar code for the programs described in section 7, as well as for several other programs listed in the manual. Appendix E provides reference information relative to HP-41 programming and the Hewlett-Packard Graphics Language, a comparison of plotter module and Hewlett-Packard Series 80 graphics functions. Appendix F provides a series of charts and tables that are useful aids to designing direct execution and paper keyboard bar code.

A function index marked by the blue-edged pages near the end of the manual enables you to rapidly locate the primary description of each plotter module function and each of the routines in the Utility Plotting Program. Following the function index is a subject index that is useful for locating information describing a wide range of plotter module topics. An additional reference, the *HP 82184A Plotter Module Quick Reference Card*, is also provided with your module as a "memory jogger." This pocket-sized document can help you to recall operating details that you have read, but may have forgotten.

The plot illustrations used in this manual were generated using an HP 7470A plotter (option 003*).

*Option 003 on the HP 7470A Plotter allows the plotter to operate in the Hewlett-Packard Interface Loop (HP-IL).

Introduction

The HP 82184A Plotter Module enables an HP-41 Handheld Computer to control Hewlett-Packard plotting devices that operate in the Hewlett-Packard Interface Loop (HP-IL) and are compatible with the Hewlett-Packard Graphics Language (HP-GL). The plotter module allows you to control such plotting devices through the HP 82160A HP-IL Module, either directly from the HP-41's keyboard or in a running program.

The module contains 52 plotter functions (including 10 bar code functions) and the Utility Plotting Program. In addition, a line graph program and a bar chart program are included in the manual to help you get started and to provide applications programs you can modify to suit your needs.

The bar code plotting functions included in the module enable you to use your HP-41/plotter system to plot HP-41 bar code or one of three other types of bar code, and to print HP-41 bar code using the HP 82162A Thermal Printer. The interactive PLOTBC program described early in section 7 allows you to easily generate HP-41 data or program bar code on a plotter. This program is recommended for novices and for anyone who needs only to generate a series of program or data bar code rows on a page. You can use the bar code subroutines and the bar code functions (described in section 7) for designing your own bar code programs or for controlling bar code generation from the keyboard. The utility bar code functions at the end of the section enable technically advanced users to generate paper keyboard, direct execution, or non HP-41 bar code. It is not necessary to have an HP 82153A Optical Wand available when you use the plotter module to generate bar code. However, using a wand helps you to quickly verify the contents and readability of your bar code.

Installing and Removing the Module

Install the plotter module as described below, and use an HP 82160A HP-IL Module to connect your HP-41 to an appropriate plotter. (The interface loop can also contain other devices without affecting plotter operation.)

CAUTION

Be sure the HP-41 is turned off before inserting or removing the plotter module. If this is not done, the HP-41 may be damaged or its operation may be disrupted.

The HP 82184A Plotter Module plugs into any of the HP-41's ports. (If any HP 82106A Memory Modules are also plugged in, the plotter module must be in a higher-numbered port than the memory modules.) Push in the module until it snaps into place. When you remove the module, remember to place a port cap over the unused port.

Memory and Equipment Configuration

Memory Requirements and the I/O Buffer

The I/O Buffer. The module uses a block of 26 HP-41 registers to form a plotting data storage unit (termed an *input/output—or I/O—buffer*) for storing parameters used by the module to control the plotter. (The [PINIT](#) function described on page 68 creates this buffer. Most of the functions described in part II either use data stored in the buffer or change that data.)

Minimum Memory Requirements. Since the plotter module automatically controls the I/O buffer, you need be concerned *only* that there are enough memory registers available to create the buffer when you first execute **PINIT**. There is no other action you need to take concerning the I/O buffer. Of course, when determining how many registers you need available for a particular application, you need consider not only the 26 registers needed for the I/O buffer, but also how many registers you need for data storage and program memory.

Ensuring that Enough Unused Registers Are Available. To easily verify how many unused memory registers are available, press **■** **GTO** **□** **□** to pack memory, then set the HP-41 to program mode and check the number of registers indicated by the displayed **00 REG nn** message. If the number shown by **nn** is less than the number of registers you need, create the necessary additional registers by executing **SIZE** or clearing one or more programs from memory (or, if you are using the model HP-41C, by installing the HP 82170A Quad Memory Module or one or more HP 82106A Memory Modules).

I/O Buffer Permanence. Once the I/O buffer has been created, it remains in memory until you either execute the **PCLBUF** (*clear plotter buffer*) function (described on page 69) or remove the plotter module from the HP-41, then turn on the HP-41. When you perform either of these operations, the 26 registers used by the I/O buffer are restored to available memory.

What to Expect When Executing Examples. Each of the examples in this part begin with a series of keystrokes that help ensure that your HP-41 contains enough properly configured memory to perform the example. If you are relatively inexperienced at manipulating the HP-41's memory, these aids will help you learn how to anticipate memory requirements for your plotting applications.

The examples in part II do not include keystrokes for configuring memory. When you are ready to begin executing the examples in part II, if you find that you need assistance to properly configure memory, reread the preceding four paragraphs. If necessary, refer also to the description of the **SIZE** function in your HP-41 owner's manual.

The Hewlett-Packard Interface Loop

You control a plotter by using your HP-41, the plotter module, and an HP 82160A HP-IL Module. If you use more than one plotter in the loop, plotter module functions will always address the first plotter in the loop unless you use the HP-IL **SELECT** function to specify another plotter. For further information about HP-IL operation, refer to the *HP 82160A HP-IL Module Owner's Manual*.

Note: When using an HP 7470A or similar plotter, you should avoid executing plotter module functions while the plotter's VIEW function is active or while the CHART HOLD/CHART LOAD lever is in the "up" position. Executing some plotter module functions while the plotter's VIEW function is active results in a **TRANSMIT ERR** message. Execution of non-pen functions may be delayed by VIEW. Executing a pen movement function while the CHART HOLD/CHART LOAD lever is in the "up" position causes the plotter to ignore the function. Also, while VIEW is active or while the CHART lever is up, some HP-41 functions may take longer than normal to execute.

Using This Manual

For simplicity, plotter module functions (and any other functions not on the standard HP-41 keyboard) are represented by single, colored keys—such as **MOVE**. You can execute such functions in two ways: By using **XEQ** **ALPHA** *name* **ALPHA**, or by assigning the function to a key using **ASN** and pressing that key on the User keyboard. (Refer to the owner's manual for your HP-41.)

Function Descriptions

The description of each function (in part II) is preceded by a summary of information required by that function. This provides a quick, visual description of how to execute the function. For example:

MOVE

Y	y-coordinate (GUs or UUs)
X	x-coordinate (GUs or UUs)

This indicates that to move the plotter pen to a new point (defined by the current scale—which is specified in either graphic units or user units) you must place the point's y-axis coordinate in the Y-register and x-axis coordinate in the X-register before you execute **MOVE**—from the keyboard or in a program.

Displays

Unless otherwise indicated, all examples assume that you are beginning with the display cleared and set to **FIX** 4 display mode (that is, **0.0000**).

If at any time your HP-41 displays an error message, refer to appendix A, Error Messages, for an explanation of its cause. For certain conditions the error message may not be displayed until after a short delay.

Setting Up Your System for Examples

Before you begin each example, ensure that your HP-41/plotter system is ready for operation. Unless otherwise indicated, this includes a fresh sheet of paper in your plotter.

How to Use the Rest of Section 1

At various times you may need to quickly generate a standard plot. The Utility Plotting Program enables you to do so with a minimum of preparation. To see how easy this is, step through the example that follows the next heading. Or, if you are familiar with plotters and wish to begin using the plotter immediately with your own programs and keystroke routines, you may want to skip the rest of part I for now and begin reading in part II. However, if you are new to plotters, expect to use your plotter module mainly with programs written by others, or want to see further demonstrations of the plotter module's capabilities, work through the last two examples in this part. Later, if you want to begin developing your own plotting programs, you will find in part II the information you need.

The three examples that follow are intended to demonstrate the plotter module's capabilities rather than to instruct you in plotter module operation. Therefore, in each of these examples, most of the text pertains to the general progression of the example instead of to the purpose and operating details of individual functions. Instructional material is provided later, in section 2 and in part II. So, if you are ready, plug in your plotter module, connect the HP-41 to your plotter, and begin plotting!

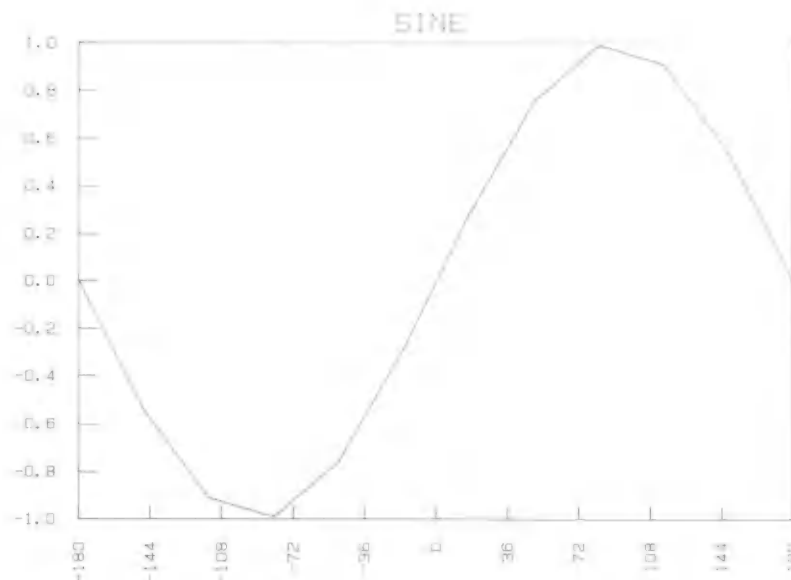

Plotting a Function

The Utility Plotting Program in your plotter module contains five plotting routines* that use your inputs to automatically generate a complete plot—that is, a plot that includes:

- A graphic representation of a math function or series of points you specify.
- A frame defining the plotting area.
- Scale annotations on the x- and y-axes.

*A *routine* in the HP-41 is a sequence of program instructions that you can execute either independently of other program instructions or as a subroutine. A *program* in the HP-41 consists of all program instructions between the top of program memory and the first **END** instruction, or between any **END** instruction and the next **END** instruction.

Utility Plotting Program Example: Generate the following plot of the sine function between -180° and 180° .

Your first step is to ensure that there are enough data registers available for use by the plotting program (R_{00} through R_{11}). While doing so you can also determine if there are enough unused memory registers for the short program used in the example (2 registers), and for the I/O buffer mentioned on page 10 (26 registers). Then load into memory a program that, given an x-coordinate (in this case, any angle between -180° and 180°), returns to the X-register a y-coordinate (in this case, the sine of the angle originally placed in the X-register). This program will be used by the plotter module's Utility Plotting Program to generate the y-coordinate of each point to be plotted. Before you execute the following keystrokes, turn your plotter off, then on, to ensure that it is set to its default graphic limits.

Keystrokes

SIZE 012

DEG

GTO \square \square

PRGM

Display

00 REG nn

Ensures that R_{00} through R_{11} are available. (Does not affect the display remaining from any of your previous HP-41 operations.)

Ensures that the HP-41 is in Degrees mode.

Packs program memory.

Switches HP-41 into Program mode. The number represented by **nn** must be 28 or greater.*

*This assumes that the I/O buffer has not been created by some other plotting operation you may have executed before turning to this example. If in doubt as to whether or not the I/O buffer currently exists, switch your HP-41 out of Program mode and execute **PCLBUF**. If the buffer exists, this function clears it and returns the registers used by the buffer to unused memory. If the buffer does not exist, **PL:PLS PINIT** is displayed. In either case, switch the calculator back into Program mode. If you still have fewer than 28 registers available, refer to Ensuring that Enough Unused Registers Are Available (page 11), before proceeding with the above example.

Keystrokes	Display	
LBL	01 LBL --	
ALPHA SINE ALPHA	01 LBL ^T SINE	Enters subroutine label.
SIN	02 SIN	Enters sine function.
PRGM	0.0000	Switches HP-41 out of program mode.

Now you are ready to begin executing the Utility Plotting Program. The HP-41 will prompt you for several parameters that control the basic plotting operation. The first parameter you will enter identifies the name of the subroutine you keyed in to calculate the y-coordinates (SINE). The next two parameters specify the lower and upper limits of the x-axis.

Keystrokes	Display	
NEWPLOT	NAME = ?	Prompts you to key in the name of the subroutine that calculates the y-coordinate of the plot.
USER		Deactivates User keyboard activated by NEWPLOT . (The User keyboard is not needed in this example. Its general use is described on page 21 in section 2.)
SINE R/S	XMIN = -1.000?	Enters function name. HP-41 prompts you to select the minimum x-axis value. (The -1.000 in the display is the default x-axis minimum that is set whenever you execute NEWPLOT without specifying a minimum.)
180 CHS R/S	XMAX = 1.000?	Enters minimum x-axis value. HP-41 prompts you to select the maximum x-axis value. (The displayed 1.000 is the default x-axis maximum.)
180 R/S	XINC = -11.000?	Enters maximum x-axis value. HP-41 prompts you to select the x-increment. (Ignore the minus sign for now.)

The preceding display prompts you to specify the number of equal increments (that is, the intervals between x-coordinates). The displayed default parameter is 11 increments.

Keystrokes	Display	
R/S	YMIN = -1.000?	Enters the displayed default number of increments. HP-41 prompts you to select the minimum y-axis value.

The next two parameters you enter specify the top and bottom boundaries of the plot.

Keystrokes	Display	
R/S	YMAX = 1.000?	Enters default y-minimum shown in the preceding display. HP-41 prompts you for y-maximum value.
R/S	PLOT?	Enters default y-maximum. The HP-41 sounds a tone and prompts you to indicate whether or not to generate a plot.

You have now specified the source of the y-coordinates for your plot, the number of equally-spaced x-increments, and the scale and boundaries of your plot. The system is now ready to generate a plot.

Keystrokes

R/S

Display

PLOT?

■ [FIX] 4 ←

0.0000

Plots the sine function with appropriate chart annotation.

Prompts you to indicate whether or not to generate another plot.

Sets display mode to [FIX] 4 and clears display.

NEWPLOT and the other routines in the Utility Plotting Program enable you to easily perform complete plots using a variety of data options. Section 2, The Utility Plotting Program, describes these options and other operating details you will need to know to make full use of the program.

Plotting a Line Graph and a Bar Chart

The preceding example introduced you to your plotter module's utility plotting program. However, you may also have a need to perform unique plotting operations that are best undertaken using other, more specialized plotting programs that you create. Such programs use plotter module functions (described in part II of this manual), HP-41 functions, and, where desired, functions belonging to HP-41 extensions and/or peripherals. If you plan either to write plotting programs yourself or to use programs written by others, the following two examples will help you visualize some of the ways the plotter module can be adapted to your specific needs.

Configuring HP-41 Memory

The next example requires that you have a minimum of 80 registers available in your HP-41.* That is, 31 memory registers to hold the program, 26 unused registers (for the I/O buffer mentioned on page 10), and 23 data storage registers. The next keystroke series ensures this configuration.

Keystrokes

■ [GTO] [] []

[SIZE] 023

[PCLBUF]

Display

0.0000

0.0000

0.0000

Packs program memory.

Ensures that R₀₀ through R₂₂ are available.

If the I/O buffer remains from an earlier plotting operation, this function restores to unused memory the registers used by the buffer. If no buffer exists, the message **PL:PLS PINIT** is displayed.

[PRGM]

00 REG nn

Switches the HP-41 to Program mode. The number of registers indicated by *nn* must be 57 or more. If not, refer to Ensuring that Enough Unused Registers Are Available, page 11.

[PRGM]

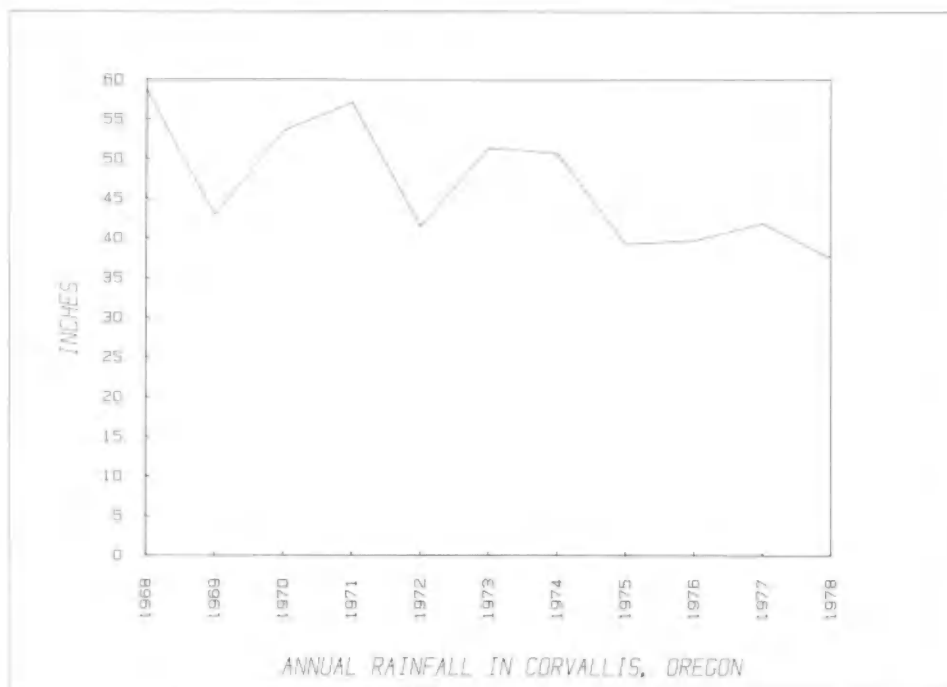

0.0000

Removes HP-41 from Program mode.

Line Graph Example

Suppose you wanted to plot the average annual rainfall in Corvallis, Oregon, for the 11-year period from 1968 through 1978. You could write and load into program memory an independent program that plots years on the *x*-axis and inches on the *y*-axis. (That is, a program that does not use the plotter module's built-in Utility Plotting Program.) Press ■ [GTO] [] [] and load the RAIN program from either the bar code on page 203 or the program listing on page 160. Then execute RAIN and key in the rainfall for each year. When you press the keys shown on the next page, the plotter generates a graph like the following:

*If you are using a model HP-41 C, you will need one HP 82106A Memory Module or the HP 82170A Quad Memory Module.

Before you execute the following keystrokes, turn your plotter off, then on, to ensure that it is set to its default graphic limits.

Keystrokes

XEQ ALPHA RAIN
ALPHA

58.73 **R/S**

42.92 **R/S**

53.60 **R/S**

57.15 **R/S**

41.56 **R/S**

51.44 **R/S**

50.76 **R/S**

39.33 **R/S**

39.73 **R/S**

41.91 **R/S**

37.64 **R/S**

Display

1973=?

1974=?

1975=?

1976=?

1977=?

1978=?

0.0000

Executes RAIN. HP-41 prompts for the 1968 rainfall.

Enters rainfall for each displayed year, then prompts for the next year.

Enters rainfall for final year, then plots graph. Plot completed.

Bar Chart Example

This example requires that you have a minimum of 78 registers available in your HP-41. If you have not altered memory since executing the preceding example, just use the following keystrokes to reconfigure memory for the next program. Otherwise, execute the keystrokes under Configuring HP-41 Memory on page 15 before you proceed with the following keystrokes.

Keystrokes

CLP ALPHA RAIN
ALPHA

SIZE 013

Display

CLP RAIN_

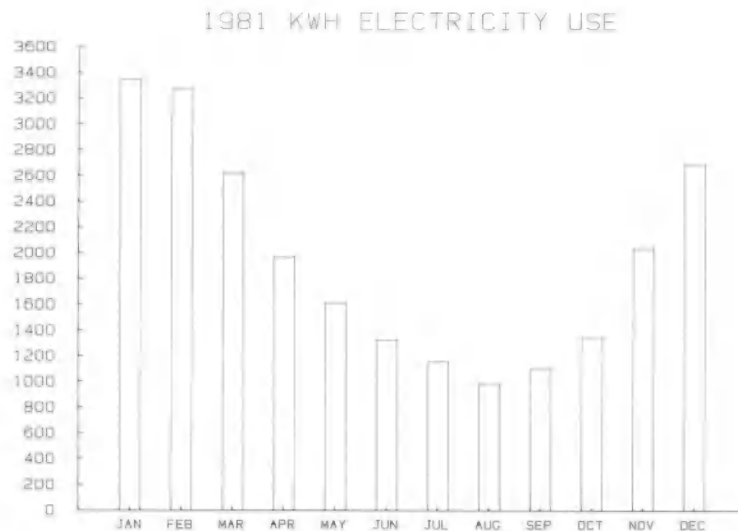

0.0000

0.0000

Clears RAIN program from memory to allow enough space for next program.

Reconfigures memory to 13 data registers (R₀₀ through R₁₂).

Suppose you wanted a bar chart showing your monthly household electrical consumption in kilowatt-hours (kwh) for 1981. You could write and load into program memory an independent program that plots months on the x-axis and kilowatt-hours on the y-axis. To illustrate, enter the KWH program from either the bar code on page 196 or the annotated listing on page 161. Then execute KWH and key in the electrical consumption in kilowatt-hours for each month. When you press the keys shown at the bottom of this page, the plotter generates the following chart.

Keystrokes

XEQ ALPHA KWH
 ALPHA
 3346 R/S
 3278 R/S
 2625 R/S
 1973 R/S
 1616 R/S
 1330 R/S
 1158 R/S
 986 R/S
 1105 R/S

 AUG
 SEP
 OCT
 NOV
 DEC

Executes KWH and prompts you to key in January's electrical consumption (in kwh).

Enters electricity consumption for each displayed month, then prompts for the next month's consumption.

Enters kwh for December, then plots the bar chart.

Plot completed.

0.0000

This concludes the plotting examples in section 1. To summarize, the first example (page 13) uses the plotter module's built-in Utility Plotting Program. The remaining two examples (pages 15 and 16) use specialized programs of the type that you can create and load into the HP-41's program memory. Each of these examples automatically created the 26-register I/O buffer when needed. If you just completed the preceding example, this buffer remains in HP-41 memory.

Returning I/O Buffer Registers to Available Memory

When you complete a plotting session, you may want to clear the I/O buffer from memory so that the 26 registers used by the buffer will be available for other HP-41 operations. (The two procedures you can use to do so are described under I/O Buffer Permanence on page 11.) If the buffer remains in your HP-41 from the preceding example (or from any other plotting operation), the following keystrokes clear the buffer.

Keystrokes	Display	
■ GTO . .	0.0000	Packs program memory.
PRGM	00 REG nn	Switches HP-41 to Program mode and displays number of unused registers (<i>nn</i>).
PRGM	0.0000	Removes HP-41 from Program mode.
PCLBUF PRGM	00 REG nn	Clears I/O buffer from memory, then returns HP-41 to Program mode. Number of unused registers (<i>nn</i>) has increased by 26 because I/O buffer has been cleared.
PRGM	0.0000	Removes HP-41 from Program memory.

Where To Read Next?

The example on page 13 introduces you to the plotter module's built-in Utility Plotting Program. If you wish to learn the details of how to use this program, turn to section 2.

The RAIN and KWH examples demonstrate the kinds of results that can be achieved with user-designed programs. If you wish to learn about the individual plotter module functions that are provided for use in such programs, turn to part II, which begins on page 63.

Introduction

The HP 82184A Plotter Module's Utility Plotting Program generates complete plots—that is, framed, labeled plots of functions or data. This program enables you to use the plotter module in many applications *without* having to first learn how to use the plotter module's individual functions. If you are generally unfamiliar with plotter operation or want to learn how to quickly generate some of the more common types of plots, reading through this section may be the best way for you to proceed. When you are ready to learn how to use the plotter module's individual functions in your own programs or in step-by-step plotter control operations from the HP-41 keyboard, turn to part II, which begins on page 63.

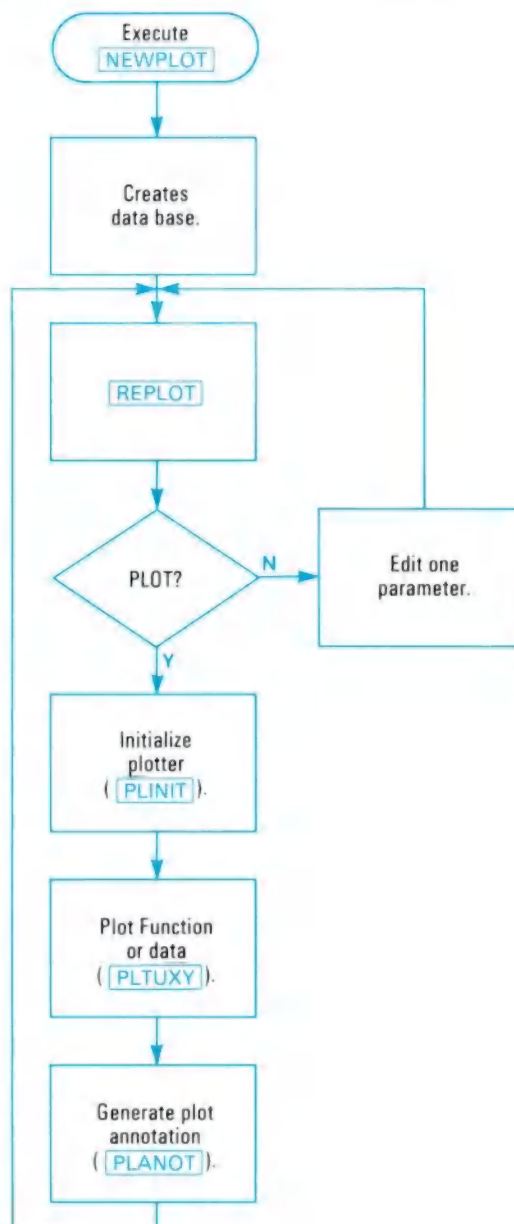

Program Overview

The Utility Plotting Program in your plotter module contains five major routines:

1. **NEWPLOT** (*new plot*) enables you to prepare for plotting by prompting you for several parameters, automatically assigning several other default parameters, and transferring execution to the **REPLOTT** routine. **NEWPLOT** uses data registers R₀₀ through R₁₁ as a *plotting data base* that contains the plotting parameters.

2. **REPLOT** (*review/plot*) prompts you with **PLOT?**, to perform either of the following operations:
 - Automatically generate a complete plot by sequentially executing the **PLINIT**, **PLTUXY**, and **PLANOT** routines, then return to the **PLOT?** prompt. (This choice is demonstrated in the example of plotting a function on page 13.)
 - Review and, if desired, edit the contents of any register in the plotting data base (R_{00} through R_{11})—or any other data storage register—then return to the **PLOT?** prompt.
3. **PLINIT** (*plotter initialize*) initializes your plotter according to the parameters entered in the plotting data base during execution of **NEWPLOT** and/or **REPLOT**.
4. **PLTUXY** (*plot user x, y*) plots a function or data specified by parameters you have entered in the plotting data base.
5. **PLANOT** (*plot annotation*) draws a frame around the plotting area, then—guided by parameters in the plotting data base—labels the axes, and prints a plot title.

As shown in the following flowchart, executing **NEWPLOT** automatically executes the other routines, in order, to generate a complete plot.

To best understand how to use the Utility Plotting Program you should learn how the routines are used to set up and generate a plot, and learn how to select plotting parameters that give you the results you want. This section can help you make a good start. However, because the Utility Plotting Program offers numerous options for plot generation, the best way for you to truly master the program is to work through this section, then use it as a reference while you experiment with various combinations of plotting parameters. This procedure can help you to develop an insight into what is needed for any set of plotting requirements and to understand how the parameters interact to meet those requirements.

The preceding flowchart and the example on page 13 introduce you to the use of the five plotting routines in an automatic series. However, you can also execute any of these routines individually to perform only certain parts of the overall plotting procedure. This feature is useful, for example, when you want to plot two or more functions on a single page. In such cases it is often necessary to initialize the plotter and plot the annotation only once. The information following the next heading describes how to quickly execute the individual routines in order to perform such operations. The choice as to when to use any single plotting routine depends on your plotting applications. You will be better able to make such choices after you read through the detailed descriptions of the plotting parameters and routines provided later in this section. Appendix C, Program Documentation, includes an individual flowchart for each of these routines.

User Keyboard, Key Assignments, and Keyboard Overlay

Executing **NEWPLOT** activates the User keyboard.* Whenever the HP-41 is set to any program and the User keyboard is active, if you press a top-row key to which you have not already assigned a program label or HP-41 function, the HP-41 begins searching in the current program for the (default) local label corresponding to that key. (Local labels are described in your HP-41 owner's manual.) You can access **NEWPLOT**, **REPLOTT**, **PLINIT**, **PLTUXY**, and **PLANOT** using local labels, as shown in the illustration below. For this reason, when the User keyboard is active, you can use the top row keys to execute each of these routines so long as the HP-41 is currently set to any program line in the Utility Plotting Program. (Since all five of the plotting routines are within the same program, setting the HP-41 to any of them automatically includes all five of them in the "current program."†)

Utility Plotting Program User Keyboard

Plotting Routine:	NEWPLOT	REPLOTT	PLINIT	PLTUXY	PLANOT
Corresponding Local Label:	(LBL A)	(LBL B)	(LBL C)	(LBL D)	(LBL E)
Corresponding Top Row Key:	Σ+	1/x	√x	LOG	LN

The preceding key assignments, plus ten other assignments designed for use with the **PLOT?** prompt (in **REPLOTT**) for editing data base parameters, are printed on the keyboard overlay shipped with your plotter module.

*Line 03 of the **NEWPLOT** program sets flag 27, which is the HP-41's User keyboard flag. (Refer to the listing of **NEWPLOT** on page 162 and to the section describing flags in your HP-41 owner's manual.)

†In the HP-41, all program lines between two consecutive **END** instructions constitute a "program." Thus, a program may contain several smaller, functionally separate "routines." The five routines that form the Utility Plotting Program are within the same program in your plotter module. When you set the HP-41 to any program line, the "current program" consists of all program lines between the preceding and following **END** instructions.

The `NEWPLOT` and `RELOT` routines introduced on page 19 enable you to set and edit plotting parameters. The `PLINIT`, `PLTUXY`, and `PLANOT` routines use the plotting parameters to generate a plot. Let's examine `NEWPLOT`, `RELOT`, and the parameters they control; then, after working through a pair of examples illustrating these topics, we'll examine the remaining three routines in the Utility Plotting Program.

The remainder of this section is divided into five units that describe the Utility Plotting Program's five plotting routines. The various parameters are described with the routines by which they are entered (`NEWPLOT` or `RELOT`). The use of these parameters is described with the routines which they control. Thus, to learn, for example, the different kinds of XINC parameters you can use, turn to the `NEWPLOT` routine, which is the next topic in this section. To learn how XINC controls the plotting of points, turn to the `PLTUXY` routine, which describes how `PLTUXY` acquires coordinates and plots points.

The `NEWPLOT` Routine

`NEWPLOT` is designed for use whenever you want to establish a new set of parameters in the plotting data base. It requires that you enter at least one parameter and enables you to enter up to six parameters.

The Plotting Data Base

`NEWPLOT` uses R_{00} through R_{11} in your HP-41 as a *plotting data base*. Each time you execute `NEWPLOT` it replaces any values currently in the data base with up to 12 default plotting parameters, depending upon how many parameters you enter in response to `NEWPLOT` prompts.

Note: The plotting data base is not protected from access by the HP-41 `STO` function. Thus, you should be careful to not accidentally alter the contents of the data base if you temporarily halt a plotting session to perform other HP-41 operations involving `STO`.

How to use `NEWPLOT`

`NEWPLOT` operation proceeds as described in the following four steps:

1. Activates the User keyboard.
2. Prompts you to specify the limits of the axes and to name the source of the x- and y-coordinates of each point to be plotted. Possible source names include:
 - An Alpha string that matches the label of a subroutine (where the subroutine generates an x- or y-coordinate).
 - A number specifying a block of HP-41 data registers (termed a *plotting buffer*) containing the coordinates for a series of points you wish to plot. The number is termed a *buffer pointer*. (Plotting buffers are described in detail under Plotting From Buffers on page 48.)
 - A subroutine that prompts you to key in a y-coordinate.
3. Automatically sets an additional six plotting parameters to default values.
4. Transfers execution to the `RELOT` program, where you can generate a complete plot or inspect the contents of any data registers, including those in the plotting data base.

The example on page 13 uses `NEWPLOT` to automatically generate a complete plot. The following table illustrates each `NEWPLOT` prompt and the types of parameters you can enter in response to these prompts. The table also illustrates the `PLOT?` prompt, which is displayed after execution transfers from `NEWPLOT` to `RELOT`. Following the table are detailed descriptions of the parameters you can enter in response to `NEWPLOT` prompts.

NEWPLOT Prompts and Options for Response

Step	Instructions	Keystrokes	Resulting Display
1	Execute the NEWPLOT routine. Note: When NEWPLOT prompts you with NAME=? , your HP-41 is automatically set to the Alpha keyboard.	NEWPLOT	NAME= ?
2	Enter an Alpha string corresponding to the label of a subroutine that either returns y for a given x or prompts you to key in y; or enter a buffer pointer containing the beginning (bbb) and ending (eee) register numbers and buffer type (t). (For a description of buffer pointers, refer to How to Access a Buffer, page 49.)	<i>label</i> R/S or ALPHA <i>bbb.eeet</i> R/S	XMIN=-1.000?
3	Specify -1 for the x-axis minimum; or enter the x-axis minimum.	R/S or <i>xmin</i> R/S	XMAX=1.000?
4	Specify 1 for the x-axis maximum; or enter the x-axis maximum.	R/S or <i>xmax</i> R/S	XINC=-11.000?
5	Specify 11 equal intervals between x-coordinates (that is, 12 equally-spaced points); or enter the desired number of equal x-intervals (-n) or enter the interval (int) you want between equally-spaced x-coordinates. or enter an Alpha string corresponding to the label of a subroutine that prompts you for x (or computes x).	R/S or <i>n</i> CHS R/S or <i>int</i> R/S or ALPHA <i>label</i> R/S	YMIN=-1.000?
6	Specify -1 for the y-minimum; or key in the y-minimum.	R/S or <i>ymin</i> R/S	YMAX=1.000?
7	Specify 1 for the y-maximum; or key in the y-maximum.	R/S or <i>ymax</i> R/S	PLOT?
8	To automatically generate a complete plot, press R/S .*	R/S	PLOT?

* After you execute step 7, **NEWPLOT** automatically sets six additional default parameters to default values and then transfers execution to the **REPLOTT** routine, which is indicated by the **PLOT?** prompt.

The NAME and XINC Parameters

The NAME and XINC parameters are used by `PLTUXY` to obtain the x- and y-coordinates for the points in a plot. XINC determines the x-coordinates;* NAME determines the y-coordinates. (`PLTUXY` iterates once for each point in a plot.) Thus, your choice of parameters to use for NAME and XINC depends upon the source of the x- and y-coordinates of the points you want to plot.

The NAME Parameter. `PLTUXY` uses an Alpha-string NAME parameter to identify and execute a subroutine that determines the y-coordinate corresponding to each x-coordinate used in a plot. (That is, for each x-coordinate generated using XINC, NAME provides a corresponding y-coordinate.) As indicated in step 2 of the preceding table, the NAME parameter can be an Alpha string that matches the label of a subroutine that either calculates y or simply prompts you to key in y. (There is a subroutine built into your plotter module for this purpose. For further information, refer to Prompting For Coordinates: The X? and Y? Subroutines, page 41.) Thus, when you want the HP-41 to *calculate* y, write and enter in program memory a subroutine that, when given an x-coordinate in the x-register, calculates the corresponding y-coordinate and leaves it in the X-register.

A buffer pointer entered in response to the `NAME?` prompt is used to determine either y-coordinates only or both the x- and y-coordinates.

The XINC Parameter. Whenever NAME is used only to specify the source of y-coordinates in a plot, XINC specifies the x-coordinates. When you use a *numeric* XINC parameter—that is, a value that specifies either the equal interval between x-coordinates (*int*) or the number of equal intervals (*-n*)—the XMIN and XMAX parameters become the leftmost and rightmost x-coordinates in the plot. As indicated in step 5 of the preceding table, you can also use for XINC an Alpha string corresponding to a subroutine label. The subroutine can be designed either to prompt you to key in an x-parameter† or to calculate an x-parameter. When you execute `NEWPLOT`, if you do not specify an XINC parameter, XINC is set to the -11.000 default value (that is, *-n*, or 11 equal intervals) indicated at step 5 in the preceding table.

Note: When `PLTUXY` is executed, if XINC was specified as *-n*—the number of x-axis intervals—`PLTUXY` always changes this value to *int*—the equal interval between x-coordinates.‡ Also, when the NAME parameter is a buffer pointer that determines *both* the x- and y-coordinates, the XINC parameter is ignored.

The XMIN, XMAX, YMIN, and YMAX Parameters

These define the limits of the axes and control plotting scale. When you execute `NEWPLOT`, they are set to the default values indicated in the preceding table unless you key in your own parameters.

Automatic Transfer to `REPLOT`

The NAME, XINC, XMIN, XMAX, YMIN, and YMAX parameters control the basic configuration of all plots. The remaining six parameters (to be described later in this section), which `NEWPLOT` automatically sets to default values, either control optional plotting features or provide internal control or storage for various operations performed by `PLTUXY`. At the completion of `NEWPLOT`, program execution automatically transfers to the `REPLOT` program and prompts you with `PLOT?`. If you need to edit any of the parameters that were either specified by you during execution of `NEWPLOT` or were automatically set by `NEWPLOT` to default values, you can do so using `REPLOT`.

* Unless both x and y are obtained from a buffer identified by the `NAME?` parameter.

† Refer to the first footnote on page 41.

‡ This conversion consists of replacing *-n* with a value representing the quotient of the expression $(XMAX - XMIN) / (-n)$.

The **REPLOT** Routine

REPLOT provides a convenient method for you to review or edit the contents of the plotting data base in R_{00} through R_{11} (as well as the contents of any other data storage register and to automatically generate a complete plot. The editing feature is especially useful when you want to edit any of the default parameters you are not prompted for during **NEWPLOT** execution.* Four of these parameters are used to control plotting options that are described later in this section. (The remaining two parameters are automatically maintained for internal use by the Utility Plotting Program and should not normally be changed in any way by users.)

When to Use **REPLOT**

Whenever you want to edit an existing plotting data base or begin automatic generation of a complete plot, if the **PLOT?** prompt is not already displayed, execute **REPLOT** to display this prompt.

How to Use **REPLOT**

The **PLOT? Prompt.** Whenever **REPLOT** is executed, the HP-41 displays **PLOT?** At this point you can do any one of the following:

- Automatically generate a complete plot. To do so, press **R/S**. (When plotting is completed, the HP-41 returns to **REPLOT** and prompts you again with **PLOT?**.)
- Examine and, if you wish, edit the contents of any register in the plotting data base (R_{00} through R_{11}) or any other data storage register, then return to the **PLOT?** prompt. This operation is described under the Register Editing Procedure, below.
- Switch from automatic plotting control to individual plotting control. (That is, instead of pressing **R/S**, which causes **REPLOT** to execute **PLINIT**, **PLTUXY**, and **PLANOT** in an automatic sequence, you can manually execute one or more of these routines from the keyboard.) Under manual control of **PLINIT**, **PLTUXY**, and **PLANOT**, the HP-41 does not return to the **PLOT?** prompt in **REPLOT** unless the User keyboard is active and you are executing these routines by using the keys to which they are assigned. (If the HP-41 halts without displaying the **PLOT?** prompt, you can return to this prompt by executing **REPLOT**.)
- Execute a program that is stored in the HP-41's program memory and automatically return to the **PLOT?** prompt. To do so, press **ALPHA** to activate the Alpha keyboard, key in the program's global Alpha label, and press **R/S**.

The flowchart on page 20 illustrates the first two of the preceding options. The third option involves selective execution of **PLINIT**, **PLTUXY**, and **PLANOT**. (If you wish to selectively edit **PLINIT**, **PLTUXY**, and/or **PLANOT**, you should first refer to the description of the **PLINIT** routine on page 38.)

The Register Editing Procedure. To use this feature you must know which register in the plotting data base contains the parameter you want to edit. The following chart lists data base registers with their corresponding parameter names and **REPLOT** prompts. Several of these parameters are user-accessible when **NEWPLOT** is executed and are described in the table on page 23 and in the paragraphs following that table. The descriptions of parameters that are user-accessible only when **REPLOT** is executed begin following the tables on the next two pages.

*Refer to item 3 on page 22, and to the lower portion of the table on page 26.

The Data Base

Access	Storage	Parameter	REPLOT Prompt	Refer to Page
NEWPLOT or REPLOT	R ₀₈	Alpha String or Buffer Pointer	NAME=label? or n?	24
	R ₀₀	X-Minimum	XMIN=n?	24
	R ₀₁	X-Maximum	XMAX=n?	24
	R ₀₅	X-Increment	XINC=n?	24
	R ₀₄	Y-Minimum	YMIN=n?	24
	R ₀₇	Y-Maximum	YMAX=n?	24
REPLOT Only	R ₀₂	Plot Parameter	PLTPRM=n or label?	29
	R ₀₃	Annotation Control	ANNOT=n?	28
	R ₀₆	X-Axis Intercept	XAXAT=n?	24
	R ₀₉	Y-Axis Intercept	YAXAT=n?	24
	R ₁₀	Current X	R10=n?	—
	R ₁₁	Point Counter	R11=n?	—

A **REPLOT** prompt for a data storage register numbered higher than R₁₁ is similar to those illustrated for R₁₀ and R₁₁.

The plotter module keyboard overlay quickly shows you which digit key to press (while **PLOT?** is displayed) to access the plotting data base parameters (in R₀₀ through R₀₉). (The parameters in R₁₀ and R₁₁ are variables that are automatically maintained by **NEWPLOT** and **PLTUXY** and are usually not of interest to users.)

When the HP-41 displays **PLOT?**, and you key in a register number and press **[R/S]**:

- If the specified register contains a plotting parameter (from R₀₀ through R₀₉ in the plotting data base), the HP-41 displays the parameter name and current value.
- If the specified register is numbered higher than R₀₉, the HP-41 displays the register number and the data contained in that register.

If, after the HP-41 displays the contents of a register, you press **[R/S]** again—*without pressing any other key*—the HP-41 returns to the **PLOT?** prompt without changing the contents of the register you specified. (This feature allows you to inspect the data in a register without changing that data.) But if you instead key in numeric or Alpha data, then press **[R/S]**, the data you keyed in replaces the current contents of that register. The following chart illustrates the register editing operation.

Register Editing Procedure

Step	Instructions	Keystrokes	Resulting Display
1	Execute REPLOT automatically or from the keyboard.	-As Appropriate-	PLOT?
2	Select the register (<i>R</i>) containing the plotting parameter or other value you wish to review or edit, then do one of the following:	<i>R</i> [R/S] then	Parameter=n? or label? or Rnn=n?

Step	Instructions	Keystrokes	Resulting Display
2 (continued)	<ul style="list-style-type: none"> Retain the displayed value in the indicated register; or Store a new number in the indicated register; or Store a new Alpha string (s)—up to six characters—in the indicated register. <p>To select another register, repeat step 2. Otherwise, go to step 3.</p>	<div>R/S</div> <div>or</div> <div>n R/S</div> <div>or</div> <div>ALPHA s R/S</div>	PLOT?
3	<p>Automatically generate a complete plot (execution returns to REPLOT after plot completed);</p> <p>or</p> <p>Execute PLINIT, PLTUXY, or PLANOT. (If you execute any of these routines by pressing XEQ ALPHA <i>name</i> ALPHA, the HP-41 does not automatically return to the PLOT? prompt. Instead, when execution terminates, the HP-41 displays whatever number was left in the X-register by the routine you executed.)</p>	<div>R/S</div> <div>or</div> <div>PLINIT</div> <div>or</div> <div>PLTUXY</div> <div>or</div> <div>PLANOT</div>	<div>PLOT?</div> <div>PLOT?</div> <div>or</div> <div>variable</div>

Note: During register editing, if you accidentally key in an Alpha string for any parameter when a numeric parameter was required (or vice versa), you must terminate the entering of the erroneous data by pressing **R/S**. To correct the error, use the register editing procedure to reedit the parameter. Simply clearing the erroneous data with the **←** key, then pressing **ALPHA** to clear (or set) the Alpha keyboard does not correct the error. This is because **REPLOT** uses the numeric and Alpha entry flags (flags 22 and 23—refer to the section describing flags in your HP-41 owner's manual) to determine whether your entry was numeric or Alpha. When one of these two flags is set by a keyboard entry, it cannot be cleared by clearing the display with the **←** key.

As you can see from the Data Base chart on page 26, all parameters in the plotting data base can be accessed by **REPLOT**. To review or edit any of these parameters, use the procedure illustrated in the preceding register editing chart. The NAME, XMIN, XMAX, XINC, YMIN, and YMAX parameters are initially accessed by **NEWPLOT** and are described under The **NEWPLOT** Routine. The remaining parameters are accessed only by **REPLOT** and are described in the following text.

The XAXAT and YAXAT Parameters

The x-intercept parameter (XAXAT) is used by **PLANOT** to specify where the x-axis intercepts the y-axis. Executing **NEWPLOT** sets XAXAT to the same value that you specify for the y-minimum.

The y-intercept parameter (YAXAT) is used by **PLANOT** to specify where the y-axis intercepts the x-axis. Executing **NEWPLOT** sets YAXAT to the same value that you specify for the x-minimum.

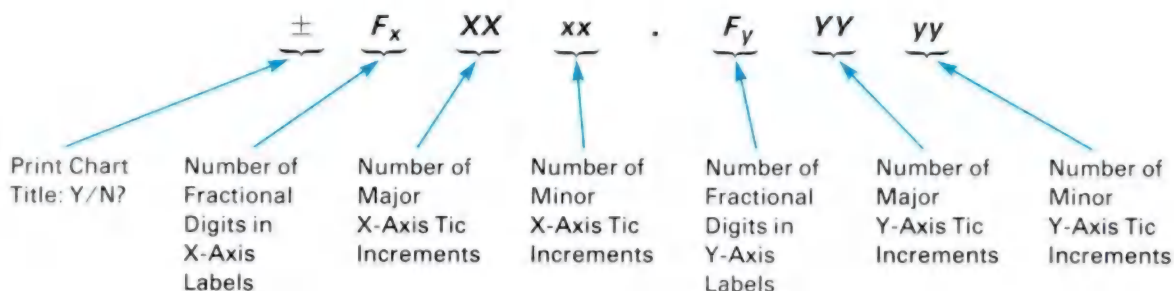

The plot generated by the introductory example on page 13 shows the results of the default x- and y-intercept parameters. The example on pages 34 through 36 uses **REPLOT** to edit these parameters.

Parameter Elements

Some plotting data base parameters contain only one data item or *element*. For example, the XMIN parameter contains one element—the minimum or leftmost limit of the x-axis. Other data base parameters contain two or more elements. The following parameter, ANNOT, contains seven elements.

The ANNOT Parameter

The annotation parameter (ANNOT) contains seven elements used by **PLANOT** to control various aspects of plot labeling. These elements are interpreted in the following format:

The Default ANNOT Parameter. **NEWPLOT** sets the annotation parameter to (0)1000.01000, which results in the following plot annotation when you execute **PLANOT**:

- If the NAME parameter (R_{08}) is Alpha data, it is printed as the plot title.
- Ten major tic increments with labels, are plotted on each axis.
- Tic labels are formatted automatically in **FIX** or **SCI** notation.
- No minor tics are plotted on either axis.

Editing the ANNOT Parameter. To change one or more elements in the annotation parameter, you must enter a complete, new parameter in R_{03} . To do so, determine all of the elements you need in the parameter to generate the desired annotation, then use the register editing procedure to access R_{03} and to enter the new parameter. The following chart describes each element of the annotation parameter.

ANNOT Parameter Elements

Parameter	Purpose
\pm	If the NAME parameter (R_{08}) contains an Alpha string, then NAME causes PLANOT to print that string as the chart title. If the NAME parameter is numeric data, no title is printed.
$-$	Suppresses chart title that would otherwise be printed if NAME contains an Alpha string.
F_x	Specifies FIX display setting for digits in x-axis labels. If $F_x = 0$, PLANOT computes an appropriate FIX or SCI setting.
XX	Specifies number of major x-axis tic increments.
xx	Specifies number of minor tic increments between major x-axis tics. (Minor tics are not labeled.) If $XX = 0$, xx specifies the number of tic increments on the x-axis.
F_y	Controls number of digits in y-axis labels in the same way as F_x does for the x-axis labels.
YY	Specifies number of major y-axis tic increments.
yy	Specifies y-axis minor tic increments in the same way that xx specifies x-axis tic increments.

To determine the major x -axis tic element to use for a given application, divide the x -axis length by the (equal) interval you want between the major (labeled) tics. Use the same procedure for the major y -axis tics and the minor tics used in both axes.

If you specify zero for either the F_x or the F_y parameter, the **PLANOT** program determines the display setting as follows:

- Where the *complete* tic label (all digits) can be printed using a **FIX** display setting of 0 through 5, the appropriate **FIX** display setting is automatically determined.
- Where i is the increment between major tics:

If

$$i \geq 10,000$$

or

$$i < 0.0001$$

the major tic labels on the applicable axis are printed in the **SCI** 4 format.

If

$$0.0001 \leq i < 10,000$$

and there are more than five fractional digits in the increment, the labels are likewise printed in the **SCI** 4 format.

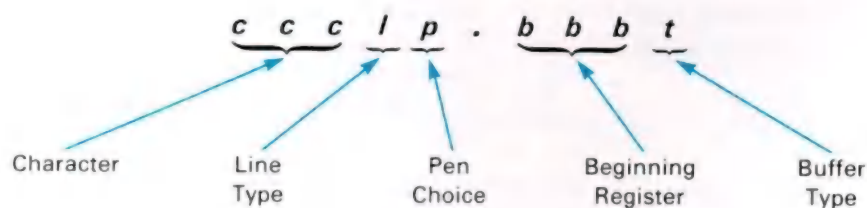

The plot illustration in the introductory example on page 13 demonstrates the result of the default annotation parameter. The entry of non-default annotation parameters are shown on pages 35, 44, and 46.

The PLTPRM Parameter

As indicated in the introduction to this section, the **PLTUXY** program is the part of the plotting package that actually plots the function or series of points you specify. **PLTUXY** uses the PLTPRM parameter to control one or more of the following options:

- Line type.
- Choice of pen.
- Choice of character to draw at each point.
- Buffer filling.
- Automatic scaling (*autoscale*).
- Executing a user-defined program at each plotting point.

In its *numeric* form, PLTPRM contains five elements. The format for these elements is:

In its *Alpha* form, the PLTPRM parameter contains only one element, an Alpha string representing any global* label in your HP-41.

*A *global* label is any Alpha label except local labels A through J and a through e.

Default PLTPRM Parameters. Executing `NEWPLOT` defaults PLTPRM to line type 1 (a solid line) and pen number 1. The remaining elements are set to null values.

The following paragraphs describe the purpose and format of each PLTPRM parameter. However, some aspects of plotting under optional PLTPRM controls require an understanding of `PLTUXY` operating details. For this reason, the integration of PLTPRM options into plotting operations is provided later, under The `PLTUXY` Routine, page 39.

The Character, Line Type, Pen, and Buffer-Filling Options. When you use numeric PLTPRM parameters, the integer portion of PLTPRM specifies the character (if any) to plot at each point, the line type, and the pen choice.

ccc is the ASCII decimal code* of the single character that can be printed at each point in a plot. Executing `NEWPLOT` defaults *ccc* to zero. The character code table on page 212 lists the characters you can select and their equivalent *ccc* code.

l specifies the line type used to connect points in your plot. (Refer to the description of the `LTYPE` (line type) function on page 89.)

p specifies the number of the pen stall containing the pen with which you wish to plot. (For pen stall information, refer to your plotter owner's manual.)

bbb specifies the beginning data storage register in a block of registers you wish to use for storing the coordinates of a series of points (a buffer-filling operation, which is described under Filling a Buffer, page 59).

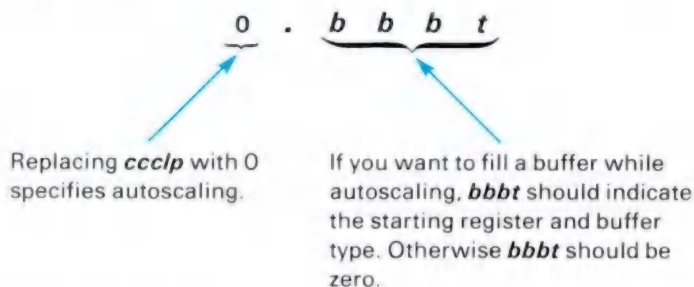

Note: The beginning register must be numbered 12 or higher. Using a lower-numbered register destroys information in the plotting data base.

t specifies the type of plotting buffer you want. Type 0 and type 2 buffers contain both the *x*- and *y*-coordinates of each point to be plotted. (A type 1 buffer contains only the *y*-coordinates of the points you want to plot.) For the purposes of this element, types 0 and 2 are identical.

When *bbbt* = 0, no buffer filling takes place.

The Autoscale Parameter. Autoscaling is designed for use either when you cannot estimate the maximum and minimum values to be derived by XINC and/or NAME accurately enough to specify the axes limits (XMIN, XMAX, YMIN, and YMAX) or when you want to fill a buffer without simultaneously plotting it.

To specify autoscaling, use register editing to set the integer portion of PLTPRM (R_{02}) to 0. That is:

When you execute an autoscaling operation, XINC and/or NAME generate *x*- and *y*-coordinates in the same way as for a plotting operation. (That is, when you specify autoscaling, `PLTUXY` generates the *x*- and *y*-coordinates, but does not plot the corresponding points.) The limits of both axes (XMIN, XMAX, YMIN,

*Characters whose decimal codes are 32 through 127 are standard printable characters as defined by the American Standard Code for Information Interchange.

and YMAX) are reset to match the respective minimum and maximum coordinates that `PLTUXY` generates. Also, PLTPRM is changed from 0 to (000)11.000 (the null character code, line type 1, pen 1, and no buffer-filling), which is the same as the default PLTPRM that is set when you execute `NEWPLOT`. Because autoscaling automatically resets PLTPRM to its default value, you can autoscale a set of parameters, then immediately generate a plot of those parameters without having to manually change any plotting parameters. Autoscaling and its relationship to `PLTUXY` is described in further detail under The Autoscale Option on page 55.

Executing a Subroutine at Each Plotting Point. When you replace the numeric `ccccp.bbbt` PLTPRM parameter with an Alpha string representing a global label, the points generated by XINC and NAME when you execute `PLTUXY` are not plotted. Instead, the subroutine named by the Alpha label in PLTPRM is executed. This option enables you to plot special shapes or diagrams at the desired points in a plot.

When you write a subroutine to be used by PLTPRM as described in the preceding paragraph, *the first instruction after the initial subroutine label should be the plotter module's `MOVE` function*. This is because `PLTUXY` executes the subroutine *after* placing the x- and y-coordinates of the next plotting point into the HP-41's X- and Y-registers.

In the example on page 34, this option is used to plot an octagon around each of several points in a plot.

Plotting Examples

The preceding discussion of PLTPRM parameters completes your introduction to `NEWPLOT`, `REPLOT`, and control of the Utility Plotting Program. The following examples illustrate the basics of how to use the program and parameters. Once you have worked through these examples you may want to begin using the Utility Plotting Program in your applications. However, if you wish to understand further details of how `PLINIT`, `PLTUXY`, and `PLANOT` use the parameters in the data base, or if you plan to use the autoscaling and buffer features, you should also read through the remaining material in this section.

Note: If you inadvertently enter the wrong data for any of the parameters in the following examples, complete the data entry as shown by the printed keystrokes, then correct the erroneous data using the register editing procedure introduced on page 25.

Keystrokes

Display

`PCLBUF`

If the I/O buffer remains from an earlier plotting operation, restores to unused memory the registers used by the buffer. Otherwise displays **PL:PLS PINIT**.

`SIZE` 013

Reallocates memory to 13 data storage registers (R₀₀ through R₁₂).

`■` `GTO` `□` `□`

Packs program memory.

`PRGM`

00 REG nn

Displays available memory. If the SINE subroutine from the example on page 13 is still in program memory, the value represented by **nn** should be at least 26. Otherwise, it should be at least 28.

`PRGM`

Removes HP-41 from program mode.

Memory Requirements. Use the following keystrokes to set up the plotting data base (R₀₀ through R₁₁) and to ensure that R₁₂ is available (for use in the last of these examples).

Example of `NEWPLOT` Operation. Use `NEWPLOT` to enter a series of plotting parameters and generate a complete plot of a sine function (in Degrees mode). Then use `REPLOT` to increase the number of points in the plot by changing the XINC parameter, and replot the function.

If the SINE subroutine used in the example on page 13 is not in your HP-41's memory, use the following keystrokes to load it into memory.

Keystrokes	Display	
<code>PRGM</code>		
<code>LBL ALPHA</code>	<code>01 LBL _</code>	
<code>SINE ALPHA</code>	<code>01 LBL TSINE</code>	Enters subroutine label.
<code>SIN</code>	<code>02 SIN</code>	Calculates sine of x-coordinate (generated by XINC and placed in X by <code>PLTUXY</code>).
<code>PRGM</code>		Removes HP-41 from Program mode.

Use `NEWPLOT` to set up the plotting data base as follows:

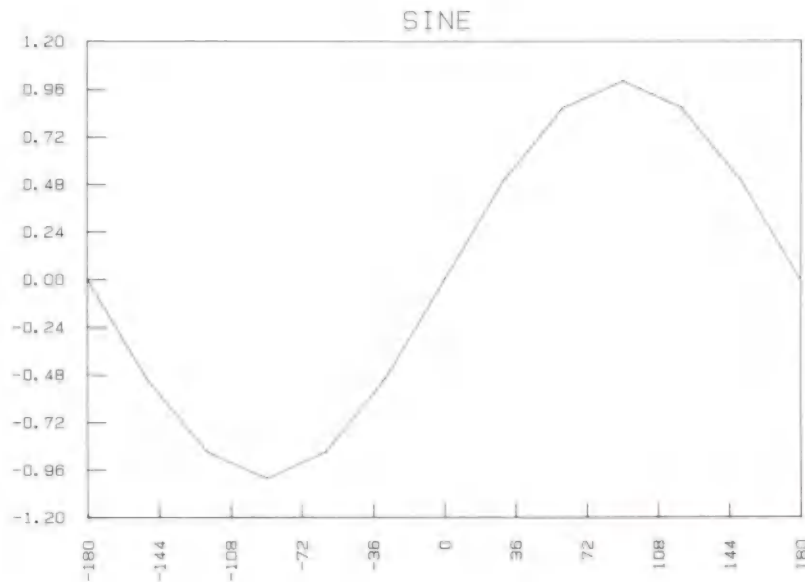

1. Set NAME to use the SINE program for determining your plot's y-coordinates.
2. Set the x-axis scale to a minimum of -180 and a maximum of 180.
3. Set the x-interval to 30. This produces the x-coordinates of the plot. The first x-coordinate is -180. The interval between succeeding x-coordinates will be 30.
4. Set the y-minimum to -1.2 and the y-maximum to 1.2.

Keystrokes	Display	
<code>DEG</code>		Ensures that the HP-41 is set to Degrees mode.
<code>NEWPLOT</code>	<code>NAME= ?</code>	Executes <code>NEWPLOT</code> program. Prompts you for parameter that names source of y-coordinate.
<code>SINE R/S</code>	<code>XMIN=-1.000?</code>	Enters Alpha string for NAME parameter. HP-41 prompts you for x-axis minimum.
180 <code>CHS R/S</code>	<code>XMAX=1.000?</code>	Enters -180 for XMIN. HP-41 prompts you for x-axis maximum.
180 <code>R/S</code>	<code>XINC=-11.000?</code>	Enters 180 for XMAX. HP-41 prompts you for x-increment.
30 <code>R/S</code>	<code>YMIN=-1.000?</code>	Enters XINC of 30. HP-41 prompts you for y-axis minimum.
1.2 <code>CHS R/S</code>	<code>YMAX=1.000?</code>	Enters YMIN of -1.2. HP-41 prompts you for y-axis maximum.
1.2 <code>R/S</code>	<code>PLOT?</code>	Enters 1.2 for YMAX. HP-41 prompts you to either generate a plot or edit the data base.

You are now ready to plot the sine function. Pressing `R/S` at this point causes the HP-41 to automatically generate a complete plot. (That is, to sequentially execute `PLINIT`, `PLTUXY`, and `PLANOT`.)

Keystrokes	Display	
<code>R/S</code>		Generates complete plot of sine function.
	<code>PLOT?</code>	Prompts you to either generate a plot or edit the data base.

The following illustration shows the resulting plot. (Leave your HP-41 turned on to preserve the `PLOT?` prompt for the next part of this example.)

Now let's plot a more accurate representation of the sine curve by increasing the number of plotting points. To do so, decrease the interval between x-axis coordinates by using the register editing procedure to change the XINC parameter (R_{05}) from 30 to 10. (Each time XINC generates an x-coordinate, NAME generates a y-coordinate.) Since the plotter is already initialized and the annotation has already been plotted (by the automatic execution of `PLINIT` and `PLANOT`), it is unnecessary to reexecute the entire plotting procedure. Instead, just replot the function by executing `PLTUXY` alone. (If your HP-41's User keyboard is active (USER annunciator displayed) and you have not assigned any function or program label to the `LOG` key, pressing `LOG` executes `PLTUXY`.)

Display remaining from preceding operation.

Displays the current XINC parameter.

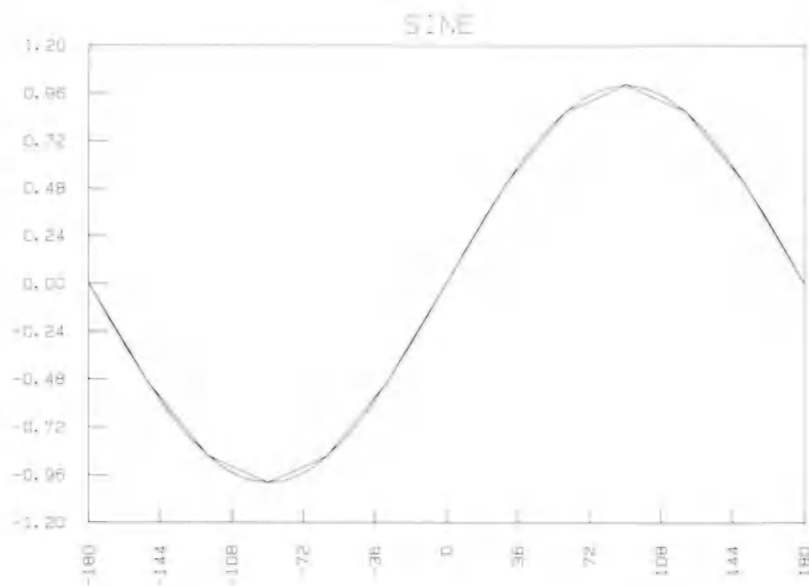

Replaces the current XINC parameter with 10. HP-41 prompts you to either generate a plot or edit the data base.

Executes `PLTUXY` to replot the sine function. (`PLINIT` and `PLANOT` are not executed.)

Plot completed.*

*Using the top row key convention described under User Keyboard, Key Assignments, and Keyboard Overlay on page 21 results in the `PLOT?` Prompt. If you do not use the top row key convention, the HP-41 displays the last number placed in the X-register before termination of the routine instead of displaying `PLOT?`.

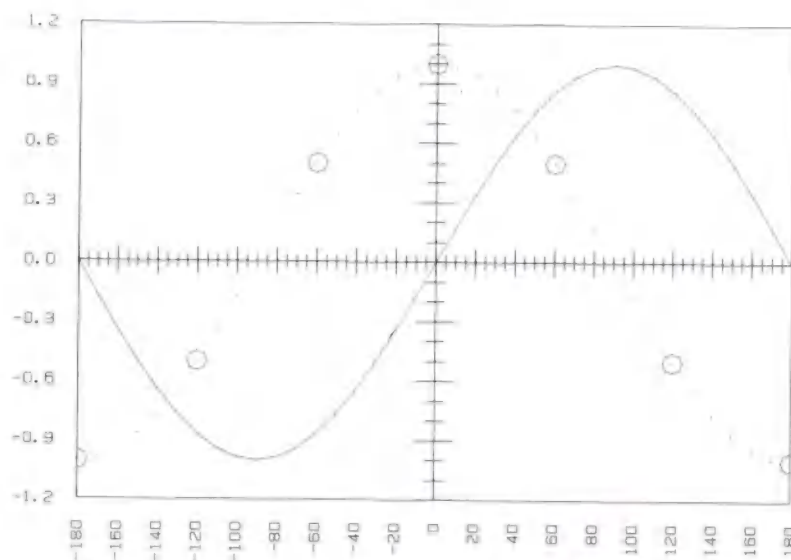

As shown in the following illustration, the sine function plot now includes a more accurately plotted curve.

Retain the plotting data base and the SINE subroutine in your HP-41's memory for use in the next example, and leave your plotter turned on to preserve the current plotter settings.

Example of Two Function Plots on the Same Page. Place a new sheet of paper in your plotter and enter in program memory a subroutine that calculates the cosine of a number. Then:

1. Adjust the plot annotation and move the positions of the axes by changing the ANNOT (R₀₃), XAXAT (R₀₆), and YAXAT (R₀₉) parameters.
2. Plot the annotation for a new chart.
3. Plot the sine function.
4. Change the line type and pen elements of the PLTPRM (R₀₂) parameter so that the plotter will use pen 2 and will plot a dotted line instead of a solid line. Change the NAME parameter (R₀₈) from SINE to COS.
5. Plot the cosine function.
6. To highlight plotting points, enter in program memory a subroutine that plots octagons around the plotting points.
7. Change the PLTPRM parameter so that it specifies the subroutine in step 6, then execute **PLTUXY** to plot the octagons.

(This example assumes that the data base and plotter settings created in the preceding example remain in your HP-41 and plotter, and that you have not assigned any functions or labels to any of the top row keys.)

 PLOT?

HP-41 prompts you for next operation.

Accesses plot annotation parameter. (Display scrolls.)

Enters new ANNOT parameter.

HP-41 prompts you for next operation.

Now change the axes intercepts to zeroes.

Keystrokes	Display	
6 [R/S]	XAXAT=-1.200	Accesses x-axis intercept.
0 [R/S]	PLOT?	Enters 0 for x-axis intercept.
9 [R/S]	YAXAT=-180.00	Accesses y-axis intercept. (Display scrolls.)
	XAT=-180.000?	
0 [R/S]	PLOT?	Enters 0 for y-axis intercept.

You are now ready to generate the plot annotation. This operation uses the parameters that you edited in the preceding keystrokes.

Keystrokes	Display	
[PLANOT]		Generates the plot annotation.
	0.0000	Plot completed.*
	-or-	
	PLOT?	

For the next step, use [PLTUXY] to generate a plot of the sine function (as specified by the SINE Alpha string entered earlier for the NAME parameter). Then switch the line type and pen number by changing the PLTPRM parameter, change the Alpha string in the NAME parameter to represent the COS subroutine, and plot the cosine function.

Keystrokes	Display	
[PLTUXY]		Plots sine function.
	0.0000	Plot completed.*
	-or-	
	PLOT?	
[REPLOT]	PLOT?	Executes [REPLOT]. (This step is unnecessary if plot is already displayed as a result of the preceding instruction.)
2 [R/S]	PLTPRM=11.000	Accesses PLTPRM parameter. Displayed parameter elements— <i>ccclp</i> = 00011—specify line type 1 and pen 1. (Display scrolls.)
	TPRM=11.0000?	
32 [R/S]	PLOT?	Enters new PLTPRM parameter that specifies line type 3 and pen 2.
8 [R/S]	NAME= SINE?	Accesses NAME parameter.
COS [R/S]	PLOT?	Enters new NAME parameter that specifies the COS subroutine.
[PLTUXY]		Plots cosine function.
	0.000	Plot completed.*
	-or-	
	PLOT?	

Now enter a subroutine labeled OCTA that plots octagons around plotting points, then edit the PLTPRM parameter so that it contains an Alpha string representing the label of this subroutine. Thus, when you reexecute [PLTUXY], it executes the OCTA subroutine at each point instead of plotting a point.

PLOT?

PLTPRM=32.000

TPRM=32.0000?

PLOT?

Enters in program memory a subroutine that plots an octagon at a point whose coordinates are given in the X- and Y-registers.

Switches HP-41 out of Program mode.

Prompts you for next plotting operation.

Accesses the PLTPRM parameter.

Enters Alpha string representing OCTA subroutine label. HP-41 prompts you for next plotting operation.

Earlier you set the XINC parameter so that a point would be plotted every 10 units on the *x*-axis. If you now execute [PLTUXY], because of the change you made to the PLTPRM parameter, octagons will be plotted at 10-unit intervals on the cosine curve, which is an unnecessarily small interval for the purposes of this example. To reduce the frequency of octagon plots, reduce the number of plotting points. To do so, increase the interval between *x*-coordinates by changing XINC from 10 to 60.

Keystrokes

5 [R/S]

60 [R/S]

Display

XINC=10.000?

PLOT?

Accesses XINC parameter.

Edits XINC. HP-41 prompts you for next operation.

You have now edited the PLTPRM and XINC parameters to plot an octagon at intervals of 60 units on the *x*-axis. If you execute [PLTUXY], it will use XINC and NAME to generate each point's *x*- and *y*-coordinates (just as it did in previous examples). However, now that the PLTPRM parameter specifies a subroutine label instead of a line type and pen number, [PLTUXY] executes that subroutine at each plotting point instead of drawing a line to the point.* (When an Alpha PLTPRM parameter is used, plotting by [PLTUXY] is done using pen 1 and line type 1.†)

*The main purpose of this example is to demonstrate parameter editing. If the use of these parameters is unclear to you at this point, you can learn more about how they affect plotting later, when you read the material under The [PLTUXY] Routine on page 39 and the [PLTUXY] flowchart on page 176.

†You can override this default by specifying another line type and pen number in the program named by PLTPRM. Refer to the [PEN] and [LTYPE] functions described under Other Pen Control Functions on page 88.

	<code>PLOT?</code>	

The `PLINIT` Routine

After `NEWPLOT` and `REPLOT` are executed, but before plotting can begin, the plotting area, scale, line type, label, and other parameters must be established in the plotter module's I/O buffer. The `PLINIT` routine automatically performs this operation for you. That is, `PLINIT` executes `PINIT`, then executes additional plotter module functions that use either the parameters included in the `PLINIT` program or the scale parameters (XMIN, XMAX, YMIN, and YMAX) in the plotting data base (R₀₀ through R₁₁) created by `NEWPLOT`. (Execution of `PLINIT` leaves the plotter module's label origin setting at `LONG` 5. Refer to changing the Label's Location, page 94.)

As described under Program Overview on page 19, each time you use `REPLOT` to generate a complete plot (by pressing `R/S` while the `PLOT?` prompt is displayed), `PLINIT` is automatically executed (followed by `PLTUXY` and `PLANOT`). Thus, the only time that you need be concerned with `PLINIT` execution is when you want to generate a plot by executing `PLTUXY` and (if needed) `PLANOT` manually from the keyboard instead of automatically under `REPLOT` control.

When to Execute `PLINIT` Manually

Once the I/O buffer has been initialized by executing `PLINIT`, it remains unchanged until you reexecute `PLINIT`.[†] Because the only plotting data base parameters (R₀₀ through R₁₁) used by `PLINIT` are the four scale parameters, it is necessary to manually execute `PLINIT` only when you are not automatically generating a complete plot. That is, you should execute `PLINIT` after you have used `NEWPLOT` to create or recreate the plotting data base, or after you have used `REPLOT` to change a scale parameter.

Controlling the Physical Size of the Plotting Area

It is not necessary to understand this topic in order to use `PLINIT` for general plotting. However, users needing to vary the size and position of plots they generate using the Utility Plotting Program should read the following information, as well as the referenced material in section II of this manual.

The actual size and position of the plotting area established by `PLINIT` depends upon the plotter you are using and the graphic limits to which your plotter is currently set.[‡] Using the HP 7470A plotter with its default graphic limits, `PLINIT` establishes a plotting area of approximately 188 mm on the x-axis and 126 mm on the y-axis. To quickly set the default graphic limits, turn the plotter off, then on, before you begin using the Utility Plotting Program.

*Refer to the footnote on page 33.

[†]Unless you execute an individual plotter module function that alters any data held in the I/O buffer. Such functions are described in part II.

[‡]The *graphic limits* define the maximum limits of pen movement. `PINIT`, which is executed by the `PLINIT` routine, sets the graphic limits to those currently maintained by your plotter. All examples in this section assume the default graphic limits, which you can set by turning your plotter off, then on, before you execute any of the plotting applications programs. Changing the graphic limits changes the size and/or the location of subsequent plots. If you wish to experiment with various sized graphic limits, refer to Graphic Limits (page 64) and Specifying the Graphic Limits (page 69).

The `PLTUXY` Routine

When you automatically generate a complete plot, the `REPLOT` program executes `PLINIT`, `PLTUXY`, and `PLANOT` for you. However, when you want to generate a plot when you don't need to reinitialize the plotter module or draw the plot annotation, just execute `PLTUXY` from the keyboard.

The `PLTUXY` routine uses the `XINC` and/or `NAME` parameters to acquire *x*- and *y*-coordinates, and the `PLTPRM` parameter to determine what to do with the coordinates. Each iteration of `PLTUXY` generates one point. `PLTUXY` automatically performs as many iterations as are required to produce all points specified by `XINC` and/or `NAME`. (The `PLTUXY` flowchart on pages 176 through 178 illustrates this operation.) Before you execute `PLTUXY`, you should perform each of the following two operations at least once:

1. Use `NEWPLOT` and/or `REPLOT` to enter the parameters you want into the plotting data base.
2. Execute `PLINIT`. (It is not necessary to execute `PLINIT` more than once in any plotting session unless one or more of the parameters controlling scale (`XMIN`, `XMAX`, `YMIN`, or `YMAX`) are changed between executions of `PLTUXY`.)

General Plotting Options

The range of possible `XINC`, `NAME`, and `PLTPRM` parameters gives you several options for `PLTUXY` use. Generally, these options include:

- Plotting a function from *x*-coordinates determined by a value in the `XINC` parameter and *y*-coordinates determined by a subroutine specified in the `NAME` parameter. The examples on pages 31 through 38 demonstrate this option.
- Plotting points where you are prompted to key in one or both coordinates of each succeeding point while the plot is in progress.
- Plotting points where either the *y*-coordinate of each point or both coordinates of each point are taken from a buffer you loaded previously.
- Building a buffer with or without simultaneously plotting it.
- Where you are unsure of the scale to use, letting `PLTUXY` determine the scale (termed *autoscaling*).
- Highlighting points in a plot by plotting a special shape or design at each plotting point.

Determining Parameter Elements

To determine the elements to use for the `XINC`, `NAME`, and `PLTPRM` parameters:

1. Identify:
 - How you want `PLTUXY` to acquire the *x*-coordinates. (That is, do you want coordinates that occur at equal intervals, coordinates that you enter when prompted from the keyboard, or coordinates stored in a buffer?)
 - How you want `PLTUXY` to acquire the *y*-coordinates. (That is, do you want coordinates derived from a calculation that returns *y* when given *x*, or do you want the coordinates derived in one of the ways mentioned above for the *x*-coordinate?)
 - What you want done with the points defined by the *x*- and *y*-coordinates. (That is, do you want them plotted and/or stored in a buffer, or used for autoscaling?*)
2. Assign to `XINC` and `NAME` the parameter elements that address the sources of your coordinates, and to `PLTPRM` the elements that indicate the plotting operation you want.

*Generating coordinates and storing them in a buffer without simultaneously plotting them requires that you specify both the buffer and autoscaling operations. However, you can also choose to autoscale without simultaneously storing coordinates in a buffer.

The following two charts identify the types of XINC, NAME, and PLTPRM parameter elements you can select, and either the sources to which they refer or the plotting operations they initiate. The charts are intended to help you visualize how to control **PLTUXY**. For descriptions of the XINC, NAME, and PLTPRM parameters themselves, refer to The NAME and XINC Parameters on page 24 and The PLTPRM Parameter on page 29, or to the subject index that begins on page 223. While you are learning how to use the parameters in these charts, it may be helpful to refer to the **PLTUXY** flowchart on pages 176 through 178. The paths through **PLTUXY** as shown by this flowchart are controlled by the values you specify for the NAME and PLTPRM parameters. In this regard, it is helpful to divide the flowchart into two parts. The upper part illustrates how **PLTUXY** acquires the coordinates of each successive point. The lower part illustrates what **PLTUXY** does with each successive point.

Note: When **PLTUXY** is ready to perform the operation(s) specified by PLTPRM, the x-coordinate of the current point is in the X-register and the y-coordinate of the current point is in the Y-register.

Parameters That Acquire X- and Y-Coordinates

XINC Options	Number of equal x-coordinate intervals (<i>-n</i>).
	Interval between x-coordinates (<i>int</i>).
	Label of subroutine that prompts for (or calculates) <i>x</i> .
NAME Options	Label of subroutine that calculates <i>y</i> for a given <i>x</i> .
	Label of subroutine that prompts for <i>y</i> .
	Buffer pointer for buffer containing only y-coordinates (<i>iii.fff1</i>).
	Buffer pointer for buffer containing both x- and y-coordinates (<i>iii.fff0</i> or <i>iii.fff2</i>).*
* When a NAME parameter buffer pointer acquires both the x- and y-coordinates of each point, the XINC parameter—which at other times is used to acquire x-coordinates—is ignored.	

Parameters That Specify What to Do With the Coordinates Identified by XINC and/or NAME

Integer Part of Numeric PLTPRM Option	Plot the points. Use nonzero <i>ccclp</i> values to determine character number, line type, and pen number. (If you do not want a character plotted at each point, use 0 for <i>ccc</i> .) Autoscale (<i>ccclp</i> = 0).
Fractional Part of Numeric PLTPRM Option	Do not build a buffer (<i>bbbt</i> = 0). Build a buffer (<i>bbbt</i> ≠ 0).
Alpha PLTPRM Parameter Option	Plot a special shape at each plotting point by executing a subroutine at each point. To do so, use for the PLTPRM parameter the global Alpha label that names the subroutine.

Plotting a Function

To plot a function:

1. Write and store in program memory a subroutine that, given an *x*-value in the X-register, calculates and leaves in the X-register a corresponding *y*-value. The subroutine should have a global label.
2. Determine the XINC (*R₀₅*) parameter that will provide the desired *x*-coordinate for each point.

3. Use `NEWPLOT` or `REPLOT` to specify:
 - The program label described in 1, above, as the NAME parameter.
 - The XINC parameter and any other data base parameters that need to be entered or edited before you begin plotting.
4. Execute `PLTUXY` either automatically or manually. (If you execute `PLTUXY` manually, ensure that `PLINIT` has been executed once since the last execution of `NEWPLOT` or change in the XMIN, XMAX, YMIN, or YMAX parameters.)

When you execute `PLTUXY`, it uses XINC to determine an x-value, places a copy of that value in the X-register, then executes the program specified by the label used as the NAME parameter. `PLTUXY` repeats this procedure for each successive point.

Prompting For Coordinates: The X? and Y? Subroutines

You can design a `PLTUXY` operation to prompt you to key in one or both coordinates of each point. The Utility Plotting Program contains two subroutines, labeled X? and Y?, that you can use for this purpose.

How to Use X? and Y?. If you want the HP-41 to prompt you to key in each successive x-coordinate used in a plot, use X? for the XINC parameter (R_{05}).^{*} If you want the HP-41 to prompt you to key in each successive y-coordinate, use Y? for the NAME parameter.

How the X? and Y? Subroutines Operate. When you use X? as the XINC parameter, each time a new x-coordinate is required `PLTUXY` executes the X? subroutine, which prompts you to key in the desired x-coordinate. `PLTUXY` keeps track of the number of points that have already been plotted and includes in the X? subroutine's prompt a number in parentheses to indicate the sequence number of the current point. The first point in any series will be point 0. Thus, the first X? prompt will be `X(0)= ?`. The Y? subroutine operates in the same way.

Terminating Keyboard Entry of Coordinates. When you are using the X? and/or Y? subroutines to prompt you for point coordinates, and you want to terminate point acquisition, wait until the next X? or Y? prompt appears, then press `R/S` without keying in a number.[†] When you do so, execution of `PLTUXY` terminates. (If `PLTUXY` was executed automatically by `REPLOT`, execution transfers to the `PLANOT` routine.)

Where only one coordinate of each point is to be entered from the keyboard, if the parameter controlling the other coordinate determines the number of points in the series, `PLTUXY` automatically terminates after processing the final point. For example:

- If NAME contains Y? and XINC contains a value specifying either the number of equal x-intervals or the interval between each x-coordinate, XINC determines the number of points that `PLTUXY` plots.

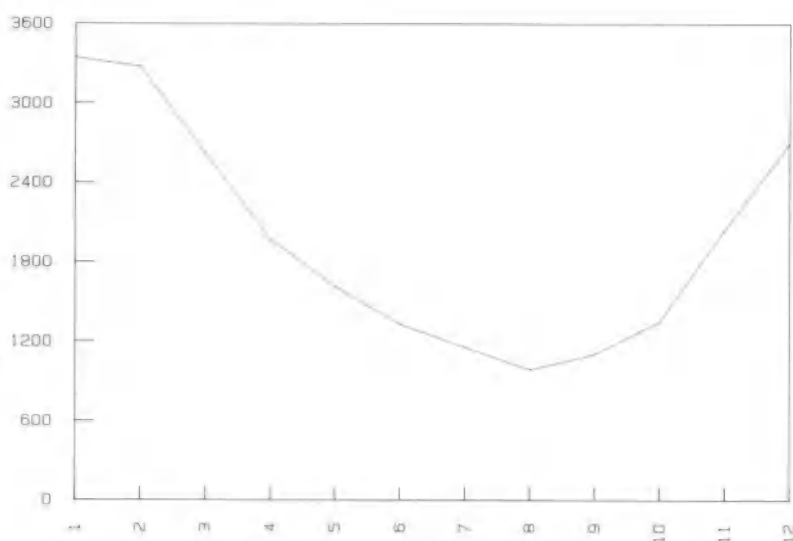

^{*}If the XINC parameter already contains a numeric element, you will have to activate the Alpha keyboard by pressing `ALPHA` before you key in the label name. If the XINC parameter already contains an Alpha element, the Alpha keyboard is automatically activated when the XINC prompt is displayed. The same applies to the NAME parameter when you are using the register editing procedure. (However, the Alpha keyboard is always activated when the NAME prompt is displayed as a result of executing `NEWPLOT`.)

[†]`PLTUXY` uses the HP-41's Numeric Input Flag (flag 22) to determine whether or not you key in a number in response to either the X? or Y? subroutine prompt. If you do not key in a number, flag 17 is set, which causes `PLTUXY` to stop generating coordinates and to halt or to transfer execution back to `REPLOT`. Thus, pressing `R/S` without a keyboard data entry terminates `PLTUXY` automatically. (If you design your own subroutine for XINC or NAME, you can use flag 17 for this same purpose.)

- If XINC uses the X? subroutine, and if NAME contains the label of another subroutine that returns y for a given x, neither parameter determines the number of points.

The first of the following two examples demonstrates **PLTUXY** operation when the Y? subroutine label is used for the NAME parameter and the XINC parameter determines the number of points plotted. The second example demonstrates **PLTUXY** operation where neither XINC or NAME determine the number of points plotted.

Example Using Y? In NAME. The bar chart example on page 16 in section 1 used a specialized program to plot kilowatt-hour electrical consumption over a 12-month period. The data supplied for that example indicates that energy consumption ranged from a low of 986 kilowatts per month to a high of 3,346 kilowatts per month. Suppose you wanted to use the same input data with the Utility Plotting Program to generate a simple line chart like the one shown below.

You can easily set up the plotter to generate the preceding chart by using **NEWPLOT** and **REPLOTT** to initialize the data base. Before you begin to plot, ensure that there are 12 data storage registers available for the plotting data base and at least 26 unused memory registers available for the I/O buffer.

Keystrokes

PCLBUF

SIZE 012

GTO [] []

PRGM

PRGM

Display

00 REG nn

Clears the I/O buffer if it exists. If the buffer does not exist, **PL:PLS PINIT** is displayed.

Ensures that R₀₀ through R₁₁ are available for the plotting data base.

Packs program memory.

Switches HP-41 to Program mode. The number of registers indicated by **nn** must be 26 or more. (If it is not, refer to Ensuring that Enough Unused Registers Are Available, page 11.)

Removes HP-41 from Program mode.

Now use the Utility Plotting Program to plot a line chart of energy consumption.

Keystrokes	Display	
<code>NEWPLOT</code>	<code>NAME= ?</code>	Prompts you to key in the name of the subroutine that calculates the y-coordinate of the plot.
<code>Y? R/S</code>	<code>XMIN=-1.000?</code>	Enters name of Y? subroutine included in Utility Plotting Program. HP-41 prompts you to select the minimum x-axis value.

Since the minimum x-axis value should represent the first month in the period, and the maximum x-value should represent the last, or 12th month in the period, use 1 for XMIN and 12 for XMAX.

Keystrokes	Display	
<code>1 R/S</code>	<code>XMAX=1.000?</code>	Enters minimum x-axis value. HP-41 prompts you for maximum x-axis value.
<code>12 R/S</code>	<code>XINC=-11.000?</code>	Enters maximum x-axis value. HP-41 prompts you for the x-increment.

The x-axis represents 12 months. Because we expect to plot one point for each month, use 1 as the increment between x-coordinates.

Keystrokes	Display	
<code>1 R/S</code>	<code>YMIN=-1.000?</code>	Enters x-increment. HP-41 prompts you for the y-axis minimum value.

Since the minimum y-axis value should represent the lower limit of the energy consumption plot and the maximum y-axis value should represent the upper limit of consumption, use 0 for YMIN and 3600 for YMAX.

Keystrokes	Display	
<code>0 R/S</code>	<code>YMAX=1.000?</code>	Enters minimum y-axis value. HP-41 prompts you for maximum y-axis value.
<code>3600 R/S</code>	<code>PLOT?</code>	Enters maximum y-axis value. HP-41 prompts you to indicate whether or not to generate a plot.

If you generate the plot now, the default ANNOT (plot annotation) parameter (set in R₀₃ of the plotting data base) by `NEWPLOT` will plot ten major tic intervals, with corresponding tic labels, on each axis. This same default parameter will print the Y? label in the NAME parameter as the plot label. Before generating the plot, use the parameter editing feature to change the ANNOT parameter to specify tics and labels that correspond to months on the x-axis and blocks of 600 kwh on the y-axis. (Specifying 11 x-axis tic intervals produces 12 labeled tics—1 through 12; specifying 6 y-axis tic intervals produces 7 labeled tics—0 through 3600.) Use the ANNOT sign convention to avoid printing a plot label (that is, use a negative parameter value).

Keystrokes

3 [R/S]

1100.006 [CHS] [R/S]

[R/S]

Display

ANNO=1000.01

T=1000.010007

PLOT?

Uses the [REPLT] register editing feature to access the ANNO parameter in R₀₃. (Display scrolls.)

Enters a value that specifies 11 tic intervals on the x-axis and 6 tic intervals on the y-axis. Because the value is negative, no plot label will be printed. HP-41 prompts you to indicate whether or not to generate a plot.

Begins automatic generation of a complete plot.

Because of the numeric XINC parameter you entered earlier, [PLTUXY] computes the x-coordinate needed for each point. However, because you used the Y? subroutine label for the NAME parameter, each time [PLTUXY] requires a y-coordinate, the Y? subroutine, which prompts you for a y-coordinate, is executed.

Y(10)=?

Y(11)=?

HP-41 prompts you for first y-coordinate (which is the first month's electricity consumption).

Enters the y-coordinate corresponding to each month's consumption, then prompts you for the next y-coordinate.

Enters 12th y-coordinate.

Because the XINC parameter you entered earlier allows 12 x-coordinates,* [PLTUXY] execution terminates, and no more points are plotted. Because [PLTUXY] was executed under automatic control, execution transfers to [PLANOT] and completes the plot.

Keystrokes

None

Display

PLOT?

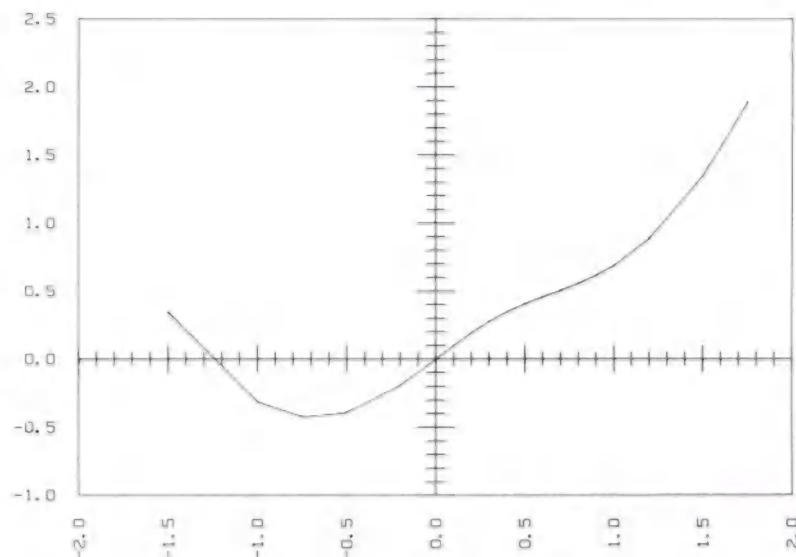

Plot completed. HP-41 prompts you to indicate whether or not to generate another plot.

Example Using Keyboard-Entered X-Coordinates. Suppose that you wanted to generate a plot of the function

$$f(x) = x^2 - \ln(x^2 + e^{-x})$$

so that the portion of the function that lies between $x = 0$ and $x = 1$ is plotted with greater precision than the remainder of the function.

*The XMIN/XMAX range is 1 through 12. As XINC specifies 1 unit between x-coordinates, the result is 12 coordinates.

To generate this plot, load into program memory a subroutine that calculates $f(x)$. Use the subroutine's label for the NAME parameter. Use the label of the Utility Plotting Program's X? subroutine for the XINC parameter. This choice of parameters enables you to key in any x -coordinate you wish when prompted by X? for each successive point. The corresponding y -coordinate— $f(x)$ —for each x -coordinate is calculated by the subroutine identified by NAME. Thus, while the plot is in the most interesting portion of the function, you can increase plotting precision by keying in x -coordinates that are closer together than the x -coordinates you enter for other portions of the plot. This method allows you to plot virtually as many points as you wish.

To begin, ensure that there is sufficient space in memory for this example (29 unused memory registers and 12 data storage registers).

Keystrokes

`PCLBUF`

`SIZE 012`

`GTO [] []`

`PRGM`

Display

`00 REG nn`

Clears the I/O buffer if it exists. If the buffer does not exist, **PL:PLS PINIT** is displayed.

Ensures that R_{00} through R_{11} are available for the plotting data base.

Packs program memory.

Switches HP-41 into Program mode. The number at the right of the display must be 29 or greater. (Refer to Ensuring that Enough Unused Registers Are Available, page 11.)

Now load into program memory a subroutine that generates $f(x)$ when x is given (in the X-register).

Keystrokes	Display	
LBL ALPHA	01 LBL _	
GRAPH ALPHA	01 LBL ^T GRAPH	Enters subroutine label.
ENTER ↑	02 ENTER ↑	
ENTER ↑	03 ENTER ↑	
CHS	04 CHS	
e^x	05 E [↑] X	
x[≥]y	06 X<>Y	
x²	07 X [↑] 2	Enters instructions for calculating the value of the expression $x^2 - \ln(x^2 + e^{-x})$.
+	08 +	
LN	09 LN	
CHS	10 CHS	
x[≥]y	11 X<>Y	
x²	12 X [↑] 2	
+	13 +	
PRGM		

Now execute **NEWPLOT** and specify an x-axis range of -2 through 2.

Keystrokes	Display	
NEWPLOT	NAME= ?	Prompts you to key in the name of the subroutine that calculates the y-coordinate of the plot.
GRAPH R/S	XMIN=-1.000?	Enters subroutine name. HP-41 prompts you to key in the minimum x-axis value.
2 CHS R/S	XMAX=1.000?	Enters XMIN value. HP-41 prompts you to key in the maximum x-axis value.
2 R/S	XINC=-11.000?	Enters XMAX value. HP-41 prompts you to select the x-increment.

Because you want to control and vary the interval between x-coordinates, specify the Utility Plotting Program's X? subroutine. When executed by **PLTUXY**, X? prompts you to key in an x-value.

Keystrokes	Display	
ALPHA X? R/S	YMIN=-1.000?	Enters X? subroutine label for XINC parameter. HP-41 prompts you for minimum y-axis value.
R/S	YMAX=1.000?	Enters default YMIN value. HP-41 prompts you for maximum y-axis value.
2.5 R/S	PLOT?	Enters YMAX value. HP-41 prompts you to generate a plot or edit a parameter.

Generating a plot now would result in a plot annotation reflecting the default ANNOT parameters (refer to The ANNOT Parameter, page 28). Also, the axes would be drawn at the bottom and the left plotting limits. To enhance the plot's readability, specify that ticks and labels be drawn at 0.5-unit intervals on both axes, and that the axes themselves be plotted at the 0 intercepts. Since the x-axis has a range of 4 units, specify 8 x-axis ticks ($4 / 0.5 = 8$). Because the y-axis has a range of 3.5 units, specify 7 y-axis ticks. Include five minor tick intervals between the major ticks on both axes. The resulting ANNOT parameter is (00)805.00705.

Keystrokes	Display	
3 R/S	ANNOT=1000.01 T=1000.01000?	Uses register editing to access the ANNOT parameter. (Display scrolls.)

Keystrokes	Display	
805.00705 [CHS] [R/S]	PLOT?	Enters ANNOT parameter.
6 [R/S]	XAXAT=-1.000?	Accesses current (default) y-intercept parameter for x-axis.
0 [R/S]	PLOT?	Enters XAXAT parameter. HP-41 prompts you to generate a plot or edit a parameter.
9 [R/S]	YAXAT=-2.000?	Accesses current (default) x-axis intercept parameter for y-axis.
0 [R/S]	PLOT?	Enters YAXAT parameter. HP-41 prompts you to generate a plot or edit a parameter.

If you press [R/S] to automatically generate the plot, you will be prompted to key in x-coordinates without having a labeled plotting area to refer to while selecting the coordinates. To provide the plot annotation *before* you begin plotting points, first initialize the plotter by executing [PLINIT], then executing [PLANOT].

Keystrokes	Display

	PLOT?	

Plotting From Buffers

For plotting purposes, a buffer is any block of consecutive HP-41 data storage registers where the initial register number is 12 or greater. A buffer can contain both the x- and y-coordinates of each point (termed an *x,y buffer*) or only the y-coordinates (termed a *y-only buffer*). If a buffer contains only y-coordinates, PLTUXY acquires the corresponding x-coordinates using the XINC parameter. As with all coordinate sources you can specify in the NAME parameter, you should think of a buffer specified in this parameter as a means by which PLTUXY acquires points. (Refer to the PLTUXY flowchart on pages 176 through 178.)

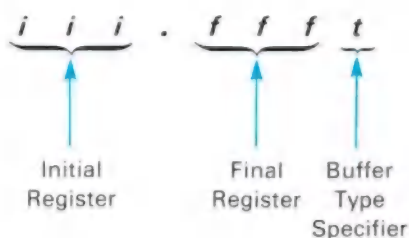

Setting Up a Buffer. To set up a buffer, first determine the number of coordinates you want the buffer to contain. Then ensure that enough storage registers exist to store the coordinates. (The first register in the block is termed $R_{initial}$, or R_i ; the last register is termed R_{final} , or R_f .) An easy way to ensure that you have enough registers is by attempting to recall the current contents of R_f to the X-register. If R_f does not exist, then execute SIZE to create the necessary number of storage registers. The last step in setting up a buffer is to store the values of the coordinates into the desired registers. You can use one of three methods to do so:

- Key in each coordinate and store it using the STO key.
- Execute REPLOTT and use the register editing feature to store coordinates.
- Execute PLTUXY with XINC and NAME parameters that acquire each successive coordinate pair, and a PLTPRM parameter that stores the points in a buffer.

Note: When Alpha data is stored in a buffer register, if you use a type 0 buffer pointer in the NAME parameter when you plot the buffer, the pen lifts when PLTUXY attempts to use the Alpha data as a coordinate for plotting a point. If PLTUXY subsequently acquires numeric data for both coordinates of a point, the pen moves to that point and drops. PLTUXY operates in this way because the plotter module's PLREGX function (described in part II) is used to plot type 0 buffers. However, PLREGX is not used to plot type 1 or type 2 buffers. Thus, an **ALPHA DATA** error message results if you attempt to plot a type 1 or type 2 buffer containing Alpha data.

*Refer to footnote on page 33.

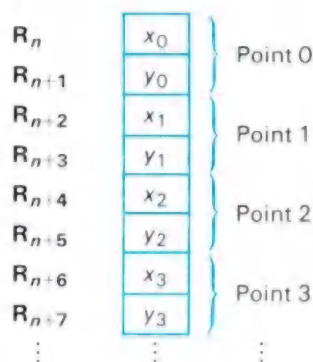

How to Access a Buffer. In order for `PLTUXY` to acquire coordinates from a buffer, you must use a buffer pointer for the NAME parameter. In a NAME buffer pointer, the integer identifies the initial buffer register (*iii*), the first three digits of the fraction identify the final buffer register (*fff*), and the fourth digit of the fraction identifies the buffer type (*t*). That is:

Buffer Types. The main purpose of specifying a buffer type is to indicate to `PLTUXY` whether the desired buffer contains both *x*- and *y*-coordinates or only *y*-coordinates. Where the buffer contains both *x*- and *y*-coordinates, the type specifier also indicates whether to plot using the character, pen, line type and buffer-filling elements specified by *ccclp* and *bbbt* in the PLTPRM parameter or to plot using only the pen and line type elements. The following paragraph describes in detail the buffer type distinctions.

When you want to use a buffer, you can choose either one of two *x/y* buffer types, or the *y*-only buffer type. The type specifiers and their corresponding buffers are:

- **Type 0.** Indicates to `PLTUXY` that the buffer contains both the *x*- and *y*-coordinates of each point to be plotted. The coordinates should be stored as shown in the following illustration.

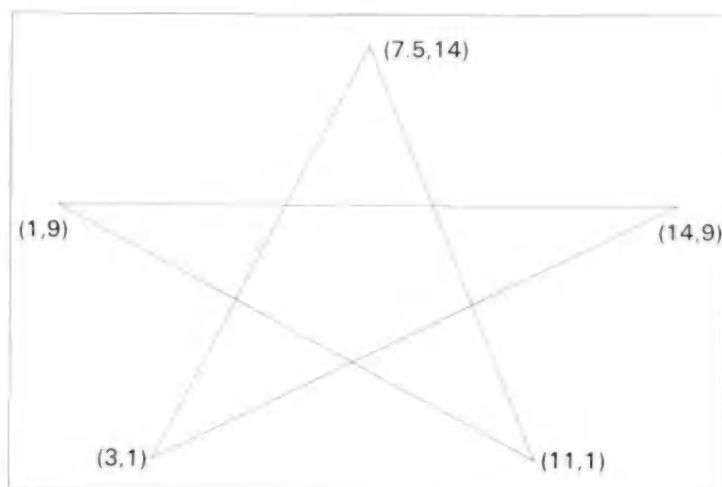

As in other types of plotting, `PLTUXY` uses the *l* and *p* elements in the integer portion of the PLTPRM parameter (*ccclp*) to determine line type and pen number. However, the *ccc* and *bbbt* elements are ignored. That is, even if *ccc* and/or *bbbt* are nonzero values, no Alpha characters will be printed at the plotted points and no buffer filling will occur. (For a description of *ccclp.bbbt*, refer to The Character, Line Type, Pen, and Buffer-Filling Operations, page 30.)

Note: If the *lp* elements are zeroes, the plotter attempts to plot the buffer without using a pen. Notice also that, because type 0 buffer plotting uses the plotter module's `PLREGX` function to plot the buffer, autoscaling is not performed by type 0 buffer plotting.

- **Type 1.** Indicates to `PLTUXY` that the buffer contains only the y-coordinates of each point to be plotted. The y-coordinate of the first point is stored in R_i ; the y-coordinate of the second point is stored in R_{i+1} , and so on. `PLTUXY` uses the `XINC` parameter to acquire the corresponding x-coordinates.
- **Type 2.** This type is interpreted by `PLTUXY` in the same way as type 0 except that the character (`ccc`), buffer-filling (`bbbt`), and autoscaling (`ccclp=0`) elements are not ignored by `PLTUXY`.*

The next two examples demonstrate how to plot using type 0 and type 1 buffers.

Example of Type 0 Buffer Plotting. Use `NEWPLOT` to define a plotting area having 15 units on each axis. Then store in R_{12} through R_{23} the coordinates for a series of points that, when plotted, form the five-point star shown below.

To plot the star, you will need, in addition to 12 data registers for the plotting data base and 26 unused memory registers for the I/O buffer, 12 data storage registers to contain the coordinates needed for plotting. The following keystrokes configure the HP-41's memory for these requirements.

Keystrokes

Display

`PCLBUF`

`SIZE 024`

`▀ GTO 0`

`PRGM`

`PRGM`

`00 REG nn`

Clears the I/O buffer if it exists. If the buffer does not exist, `PL:PLS PINIT` is displayed.

Ensures that R_{00} through R_{11} are available for the plotting data base, and that R_{12} through R_{23} are available for a plotting buffer.

Packs program memory.

Switches HP-41 into Program mode. The number at the right of the display must be 26 or greater. (If it is not, refer to Ensuring that Enough Unused Registers Are Available, page 11.)

Removes HP-41 from Program mode.

* `PLTUXY` operation with a type 0 buffer uses the `PLREGX` function described on page 83 in part II. `PLTUXY` operation with a type 2 buffer does not use `PLREGX`. When `ccclp = 0`, autoscaling occurs instead of plotting. Autoscaling is mentioned on page 30 and described later in this section, on page 55.

Now set up the plotting data base. For the NAME parameter, switch the HP-41 out of Alpha keyboard and key in the number 12.0230, which specifies a type 0 buffer using registers R₁₂ through R₂₃. Later, when you generate the plot, **PLTUXY** will acquire both the x- and y-coordinates of each point from this buffer. For this reason, no x-coordinates will be acquired through the XINC parameter, and you can therefore ignore it.

Keystrokes	Display	
NEWPLOT	NAME?	Prompts you to key in the name of a subroutine.
ALPHA 12.023 R/S	XMIN=-1.000?	Switches HP-41 out of Alpha keyboard and enters a type 0 buffer pointer. HP-41 prompts you for the minimum x-axis value.
0 R/S	XMAX=1.000?	Enters XMIN value and prompts you for maximum x-axis value.
15 R/S	XINC=-11.000?	Enters XMAX value and prompts you for the x-increment value.
R/S	YMIN=-1.000?	Leaves XINC value unchanged and prompts you for y-minimum value. (As mentioned in the preceding paragraph, XINC is not used when a type 0 buffer is specified.)
0 R/S	YMAX=1.000?	Enters YMIN value and prompts you for y-maximum value.
15 R/S	PLOT?	Enters YMAX value and prompts you to generate a plot or edit a parameter.

Unless you specify otherwise, every plot includes a default set of major tics with corresponding labels. For this plot, eliminate the tics and labels by using zero for the ANNOT parameter.

Keystrokes	Display	
3 R/S	ANNOT=1000.01	Uses register editing to access the ANNOT parameter. (Display scrolls.)
0 R/S	T=1000.01000?	
	PLOT?	Enters ANNOT parameter and prompts you to generate a plot or edit a parameter.
11 STO 12	11.000	Stores in R ₁₂ the x-coordinate of first point of star.
1 STO 13	1.000	Stores in R ₁₃ the y-coordinate of first point of star.
STO 14 9 STO 15	9.000	Stores in R ₁₄ through R ₂₁ the x- and y-coordinates of the remaining points.
14 STO 16 9 STO 17	9.000	
3 STO 18 1 STO 19	1.000	
7.5 STO 20 14 STO 21	14.000	

To close the star plot, the pen must draw a line from the last point back to the first point. Thus, the last coordinate pair in the buffer is a duplicate of the first coordinate pair.

Keystrokes	Display	
11 STO 22 1 STO 23	1.000	Stores in R ₂₂ and R ₂₃ the coordinates of the first point.

Now let's automatically generate the complete star plot.

Keystrokes

REPLOT

R/S

Display

PLOT?

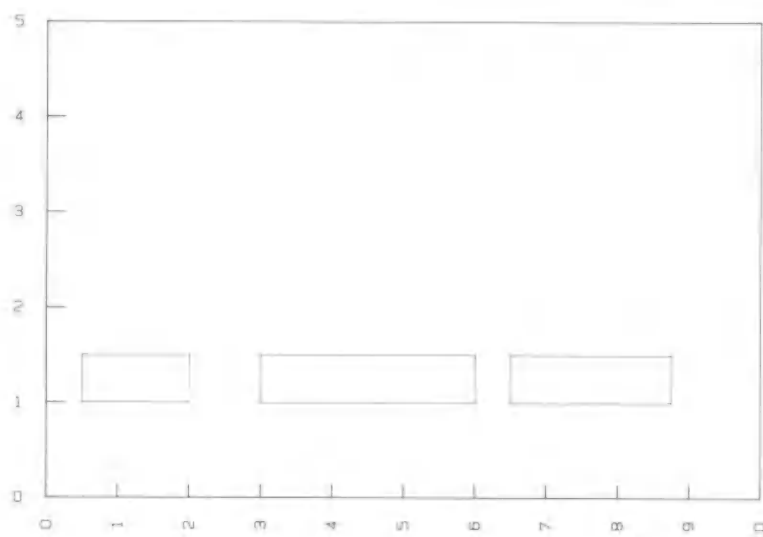

PLOT?

HP-41 prompts you to generate a plot or edit a parameter.

Generates the star plot, then prompts you as above.

In the preceding example, the XINC parameter (R_{05}), whose sole purpose is to acquire x -coordinates, was ignored by **PLTUXY** because the x -coordinates for the plot were provided in the buffer specified by the type 0 buffer pointer used for the NAME parameter (R_{08}). In the next example, which demonstrates plotting with a type 1 buffer pointer (y -coordinates only), the XINC parameter must be used for acquiring x -coordinates.

Example of Type 1 Buffer Plotting. One use of y -only buffers is to plot shapes that remain constant in the y -dimension, but vary in the x -dimension. To demonstrate, use type 1 buffer plotting to plot three windows having the same height, but differing widths.

To begin, define a plotting area 5 units high and 10 units wide. Then, set up data registers R_{12} through R_{16} as a type 1 buffer by storing in these registers the series of y -coordinates needed for a series of points that form a rectangle. Use the X? subroutine for the XINC parameter so that you can key in variables for x -coordinates.

To execute this example you will need 12 data registers for the plotting data base, 5 data registers for the plotting buffer, and 26 unused memory registers for the I/O buffer.

Keystrokes**Display**

PCLBUF

Clears the I/O buffer if it exists. If it does not exist, **PL:PLS PINIT** is displayed.

SIZE 017

Ensures that R₀₀ through R₁₆ are available for the plotting data base and for the type 1 plotting buffer.

Use **NEWPLOT** to initialize the plotting data base. Enter 12.0161 as a type 1 buffer pointer when prompted by **NAME?**. Because you want to be prompted for each x-coordinate used in the plot, use the X? subroutine label for the XINC parameter.

Keystrokes**Display**

NEWPLOT

NAME?

Prompts for a subroutine label or buffer pointer.

ALPHA 12.0161 R/S

XMIN=-1.000?

Removes HP-41 from Alpha keyboard and enters type 1 buffer pointer. HP-41 prompts for minimum x-axis value.

0 R/S

XMAX=-1.000?

Enters XMIN value. HP-41 prompts for maximum x-axis value.

10 R/S

XINC=-11.000?

Enters XMAX value. HP-41 prompts for x-increment.

ALPHA X? R/S

YMIN=-1.000?

Switches HP-41 to Alpha keyboard and enters X? subroutine label. HP-41 prompts for minimum y-axis value.

0 R/S

YMAX=1.000?

Enters YMIN value. HP-41 prompts for maximum y-axis value.

5 R/S

PLOT?

Enters YMAX value. HP-41 prompts you to generate a plot or edit a parameter.

The x-axis is 10 units long and the y-axis is 5 units long. Thus, the current annotation parameter (which is the default parameter set by **NEWPLOT**—ANNOT=1000.01000) will generate 11 x-axis ticks with integer-only labels and 11 y-axis ticks with fractional labels. Change the annotation parameter so that integer-only ticks and labels will be generated for the y-axis. (Since the NAME parameter is a numeric value, it makes no difference whether the new ANNOT parameter is given a positive or negative sign.)

Keystrokes**Display**

3 R/S

ANNOT=1000.01
T=1000.01000?

Uses the register editing feature to access the annotation parameter in R₀₃. (Display scrolls.)

1000.005 R/S

PLOT?

Enters new annotation parameter. HP-41 prompts you to generate a plot or edit a parameter.

To create the type 1 buffer needed to plot the three windows, simply store the y-coordinates in registers R₁₂ through R₁₆. Design the windows for a height of 0.5 units, with the lower corners at y = 1 and the upper corners at y = 1.5. Plan the sequence of points so that the plot for each window begins at the lower-left corner and proceeds in sequence through the upper-left, upper-right, and lower-right corners; then returns to the starting point.

Thus, you should use the following sequence when storing the y-coordinates in the plotting buffer: 1, 1.5, 1.5, 1, 1.

Keystrokes	Display	
1 [STO] 12	1.000	} Creates y-only (type 1) plotting buffer in R ₁₂ through R ₁₆ by storing y-coordinates in these registers.
1.5 [STO] 13	1.500	
[STO] 14	1.500	
1 [STO] 15	1.000	
[STO] 16	1.000	

Now generate a plot of the three windows.

Keystrokes	Display	
[RELOT]	PLOT?	HP-41 prompts you to generate a plot or edit a parameter.
[R/S]	X(0)=?	Begins plot of first window by prompting you for the first x-coordinate.

The subroutine label (X?) used for the XINC parameter causes the HP-41 to prompt you for each point's x-coordinate. Each point's y-coordinate is retrieved, when needed, from the plotting buffer you created in R₁₂ through R₁₆.

Keystrokes	Display	
.5 [R/S]	X(1)=?	} Enters x-coordinates and plots points for first window, then generates plot annotation.
.5 [R/S]	X(2)=?	
2 [R/S]	X(3)=?	
2 [R/S]	X(4)=?	
.5 [R/S]		
	PLOT?	HP-41 prompts you to generate a plot or edit a parameter.

Because the plotter was initialized and the plot annotation was generated with the first window plot, it is not necessary to perform these operations again before plotting another window in the same plotting area. Thus, instead of pressing **[R/S]** (which initiates automatic execution of **[PLINIT]** and **[PLANOT]** as well as **[PLTUXY]**) to plot the next window, just execute **[PLTUXY]**.

Keystrokes	Display	
[PLTUXY]	X(0)=?	} Enters x-coordinates and plots points for second window, then halts.
3 [R/S]	X(1)=?	
3 [R/S]	X(2)=?	
6 [R/S]	X(3)=?	
6 [R/S]	X(4)=?	
3 [R/S]	PLOT?	Plot completed.*
	-or-	
	0.0000	

*Refer to footnote, page 33.

Now plot another window in the plotting area you used for the preceding two windows.

Keystrokes

```
PLTUXY
6.5 R/S
6.5 R/S
8.75 R/S
8.75 R/S
6.5 R/S
```

Display

```

X(3)= ?
X(4)= ?
PLOT?
-or-
0.0000
```

Enters x-coordinates and plots points for third window in same manner as preceding keystroke series.

The preceding examples demonstrate plotting with type 0 and type 1 buffers specified by an appropriate pointer for the NAME parameter. Plotting with a type 2 buffer specified by NAME operates the same as with a type 0 buffer except that character plotting (*ccc* ≠ 0) or autoscaling (*ccclp* = 0), and buffer-filling (*bbbt* ≠ 0) will be performed, if specified. (Refer to Buffer Types, page 49.) Now that you have seen an example of plotting with coordinates entered singly from the keyboard, let's see how to handle such applications when it is not clear as to which axes minimums and maximums should be specified before entering coordinates.

The Autoscale Option

In plotting applications where the ranges of the x- and/or y-coordinates are not known before plotting, it is sometimes inconvenient to specify estimated maximum and minimum axis values. The autoscale (*automatic scaling*) option enables you to solve this problem by automatically resetting the maximum and minimum parameters on one or both axes to the appropriate limits—as determined by the ranges of the coordinates. PLTUXY actually acquires through the XINC and/or NAME parameters. Because the axis parameters are not reset until all x- and y-coordinates have been processed, no points are plotted during an autoscaling operation. Once you have executed PLTUXY under autoscale control to determine the limits of a plot, you can immediately generate a properly scaled plot by just reexecuting PLTUXY.

How to Specify Autoscaling. A zero value representing the entire *integer* portion of the PLTPRM parameter (*ccclp* = 0) causes PLTUXY to perform autoscaling. Thus, to specify autoscaling, execute REPLOT and use the register editing feature to replace the current PLTPRM parameter. (To simultaneously perform autoscaling and buffer-filling (which is described later, on page 59) the fractional portion of PLTPRM must also be zero.)

How Autoscaling Operates. When you execute PLTUXY under autoscale control, x- and y-coordinate pairs are generated by the XINC and/or NAME parameters in the same way as during any other execution of PLTUXY. However, when PLTPRM specifies autoscaling, PLTUXY does the following *instead* of plotting the coordinates as points:

1. Identifies the maximum and minimum coordinates for each axis.
 - If the XINC parameter is a subroutine label, or if the NAME parameter specifies a type 0 or 2 buffer (x, y buffer) the current XMIN and XMAX parameters will be reset to match the minimum and maximum x-axis coordinates. Otherwise, XMIN does not change, and XMAX is set to the x-coordinate in the rightmost point generated by PLTUXY. This is because the only remaining option for defining coordinates on the x-axis is to interpret the XINC parameter as specifying either the number of x-intervals (*-n*) between XMIN and XMAX or the interval between consecutive x-increments (*int*) bounded by XMIN and XMAX.
 - Regardless of the source of the y-coordinates, the YMIN and YMAX parameters will be reset to match the minimum and maximum y-axis coordinates.

2. After all coordinates have been generated, if the fractional portion of the PLTPRM parameter specified buffer filling (*bbbt* \neq 0), **PLTUXY** then replaces the current NAME parameter with a buffer pointer that specifies the initial and final registers of the buffer and the type of buffer (*iii. ffft*). This allows you to simultaneously autoscale and fill a buffer in one operation, then immediately plot the buffer in a second operation.
3. Resets PLTPRM to the default value originally set by **NEWPLOT**—*ccclp.bbbt* = (000)11.000. (That is, the null—*ccc* = 0—character, line type 1, pen 1, and no buffer filling.)

Note: If you specify autoscaling, then select automatic plot generation by pressing **R/S** when prompted by **PLOT?**, autoscaling occurs as described in the preceding text instead of the plot of a function or series of points. However, because automatic plot generation includes execution of **PLINIT** and **PLANOT**, the plot annotation—frame, axes, tics, and labels—will be generated.

How to Use Autoscale. To use the autoscale feature:

1. Execute **NEWPLOT** or **REPLOT** and specify data base parameters as follows:
 - Enter the appropriate NAME parameter in R₀₈. (Program label or buffer number.)
 - If the XINC parameter you plan to use is a subroutine label, or if the NAME parameter specifies an x, y (type 0 or 2) buffer, ignore the XMIN and XMAX parameters, as they will be reset by the autoscaling process. Otherwise, enter these parameters.
 - Enter the desired XINC parameter. (If the NAME parameter specifies a type 0 or 2 buffer, you can skip this step because XINC will be ignored by **PLTUXY**.)
 - Ignore the current YMIN and YMAX parameters, as they will be reset by the autoscaling process.
 - Enter zero for the PLTPRM parameter to specify autoscale.*
2. Execute **PLINIT**, then **PLTUXY**. The autoscaling process described in the preceding text takes place. No plot is generated.

Note: If you want to generate the plot annotation during this step instead of in the following step, execute automatic plot generation instead of executing **PLINIT** and **PLTUXY** individually. That is, when prompted by **PLOT?**, press **R/S**.

3. Generate a plot of the points specified by the XINC and/or NAME parameter either by executing **PLTUXY**, or by selecting automatic plot generation.

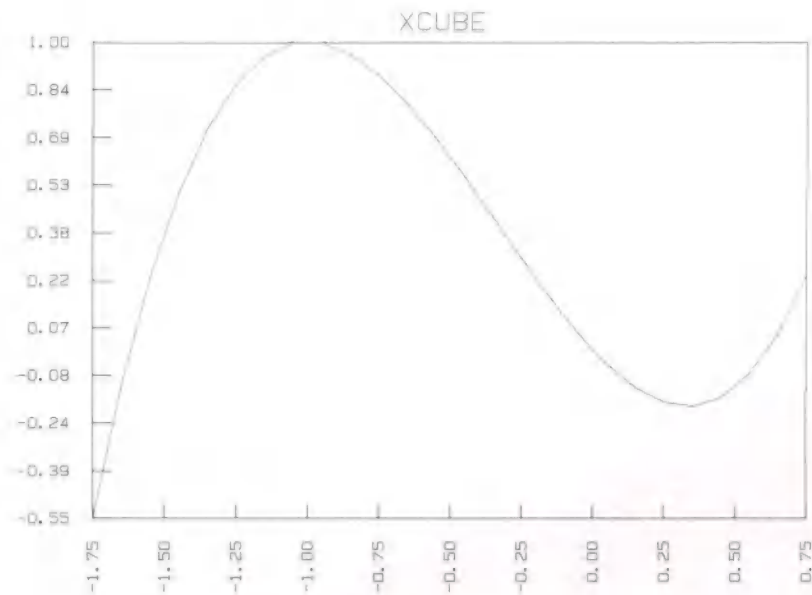

Keep in mind that between steps 2 and 3 you can change any data base parameter. In particular, you may want to use autoscaling to determine the limits of the x- and/or y-axes, then change the current axes intercepts (XAXAT and YAXAT) and annotation (ANNOT) to conform to the axes ranges resulting from the autoscaling. (Remember that if you change any of the scale parameters, you must reexecute **PLINIT** before proceeding with the plot.)

Example of Autoscaling. The function

$$f(x) = x^3 + x^2 - x$$

plots a curve that crosses the x-axis three times. Suppose that you wanted to plot this function so that the limits of the y-axis coincided with the maximum and minimum y-values between $x = -1.75$ and $x = .75$, as shown in the following illustration:

*If you wish to fill a buffer while autoscaling, the fractional portion of PLTPRM must contain the buffer data. This topic is discussed under Filling a Buffer on page 59.

You can easily determine these y-values using autoscaling. To do so, step through the following operations.

Calculates value of above-mentioned expression when given y in the X-register.

Removes HP-41 from Program mode.

Now initialize the plotter by executing **NEWPLOT**. Use the label of the preceding program as the NAME parameter. Set the x-minimum and x-maximum values to $x = -1.75$ and $x = 0.75$. To increase the plot's precision, use an equal x-increment of 0.1 ($XINC = .1$). Ignore the minimums and maximums for the y-axis. To specify autoscaling, replace the integer in the default PLTPRM parameter (R_{02}) with 0. (The default fractional portion of this parameter is also zero.)

PLOT?

Generates plot annotation, then halts.*

Filling a Buffer

As indicated earlier, x- and y-coordinates are acquired by [PLTUXY] using the XINC and/or NAME parameters. Using the buffer-filling option, you can direct [PLTUXY] to load these coordinates into a buffer. The operation can be designed to load either the x- and y-coordinates or only the y-coordinates. As you will see, buffer filling must always be combined with either a plotting or autoscaling operation.

The Buffer-Filling Pointer. This pointer, which replaces zero in the fractional portion of the PLTPRM parameter, contains (1) the beginning register of the buffer and (2) the buffer type. The pointer format is:

Because the plotting data base uses data registers R₀₀ through R₁₁, the beginning register must be a register numbered 12 or higher. As there is no final register specified, the block of registers comprising the buffer is limited only by the number of coordinates that must be stored or by the number of data registers available.

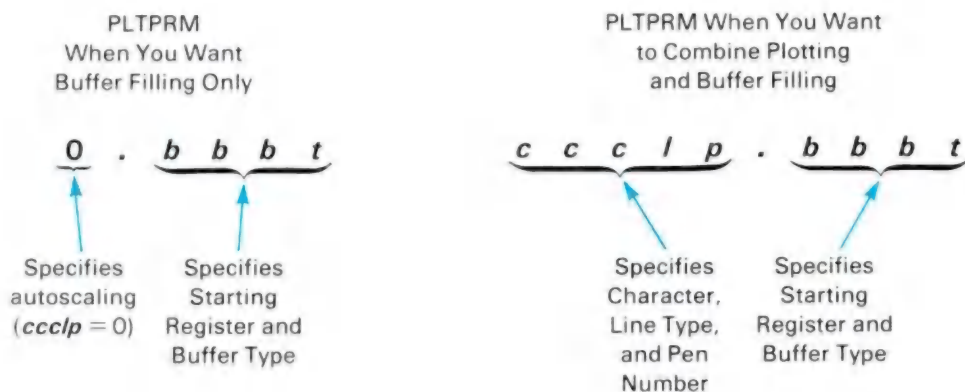

How Buffer Filling Affects the NAME and PLTPRM Parameters. When a buffer-filling pointer is used in PLTPRM, [PLTUXY] fills the specified buffer, then:

*Refer to footnote on page 33.

- Replaces the NAME parameter with an *iii.fff* buffer pointer that corresponds to the filled buffer.*
- Replaces the buffer-filling pointer in PLTPRM (*.bbbt*) with zero. (Unless you simultaneously fill a buffer and autoscale, the *ccclp* elements of PLTPRM are not changed.)

If you simultaneously autoscale and fill a buffer, these automatic changes enable you to plot the filled buffer immediately by simply executing **PLTUXY**. (Otherwise, the buffer will be plotted as it is filled.)

How **PLTUXY Uses the Buffer-Filling Pointer.** As described in the preceding paragraphs, the buffer-filling pointer forms the fractional portion of the PLTPRM parameter. The integer portion of PLTPRM is formed by *ccclp*, which determines whether plotting or autoscaling takes place when you execute **PLTUXY**. Thus, when you want to simultaneously plot points and load their coordinates into a buffer, specify a nonzero value for the *ccclp* portion of the PLTPRM parameter. When you want to load coordinates into a buffer without plotting any points (autoscaling), specify zero for the integer portion of PLTPRM.† Here are illustrations of both options:

The *ccclp* and *bbbt* parameters are unchanged by execution of **PLTUXY** unless *ccclp* is set to zero for autoscaling. (Refer to item 3 under How Autoscaling Operates on page 55.)

Buffer Type Specifiers. The type specifiers used in a PLTPRM buffer pointer to fill a buffer are the same as those used in a NAME parameter pointer to acquire coordinates from an existing buffer. (Refer to Buffer Types, page 49.) Thus, to build an *x, y* buffer, use 0 or 2 for the type specifier (*t*) in the buffer pointer. To build a *y*-only buffer use 1 for the type specifier.

Note: The *only* purpose of a type specifier following *bbb* in the PLTPRM parameter is to distinguish *x, y*-buffer filling from *y*-only buffer filling. Thus, using 2 as a buffer specifier in PLTPRM produces results identical to using 0 as a buffer specifier. This is in contrast to the use of buffer specifiers in the NAME Parameter, where type 0 and type 2 differ.

*There is one exception. If the NAME Parameter initially contains an *iii.fff0* buffer pointer (specifies a type 0 buffer), the buffer-filling pointer in PLTPRM is ignored. (Refer to Buffer Types, page 49.)

†You can plot a special shape at each plotting point instead of actually plotting the specified point. Because this option requires that you *replace* the numeric PLTPRM parameter with an Alpha subroutine label, you cannot direct PLTPRM to simultaneously fill a buffer with coordinates and plot special shapes at the points defined by these coordinates. It is possible, however, to include in the subroutine the instructions necessary to store the coordinates in the desired buffer.

The `PLANOT` Routine

The `PLANOT` routine generates a frame, axes, tics, and labels according to the parameters in the plotting data base. `PLANOT` accesses all data base parameters except `PLTPRM` and `XINC`. When you automatically generate a complete plot (refer to The `PLOT?` Prompt, page 25), the `REPLOTT` routine executes `PLANOT` after executing `PLINIT` and `PLTUXY`. However, you can execute `PLANOT` individually whenever you want to generate a plot annotation without unnecessarily reinitializing the plotter or plotting a function or series of points. (Execution of `PLANOT` leaves the plotter module's label origin setting at `LORG` 5. Refer to Changing the Label's Location, page 94.)

When to Use `PLANOT`

As indicated above, when you use automatic plot generation you don't need to think about executing `PLANOT` because it is automatically executed for you. If instead, you are plotting by individually executing routines in the Utility Plotting Program, use `PLANOT` whenever you need to annotate the plot. For example, you may want to annotate a new sheet of paper before you begin plotting on it. Also, remember to execute `PLANOT` whenever you reset `XMIN`, `XMAX`, `YMIN`, or `YMAX`. Otherwise, the scale on your plot will be incorrect.

Note: Depending upon your plotting operations, it may be necessary to execute `PLINIT` before executing `PLANOT`. For further information, refer to The `PLINIT` Routine, page 38.

`PLANOT` Operation

`PLANOT` annotates a plot by performing the following:

- Selects pen 2.
- Uses line type 1 (refer to the `LTYPE` function, page 89).
- Frames the plotting area.
- Uses the `ANNOT` parameter to determine the number of major and minor tics on each axis.
- Uses a major tic length of 2% of the appropriate axis, and a minor tic length of 1% of the appropriate axis. (For information concerning tic length calculations, refer to the `TICLEN` function on page 100 and the `PINIT` function on page 68.)
- Labels major tics on each axis in the default or specified format indicated in the annotation parameter.

For more detailed information concerning `PLANOT`, refer to the `PLANOT` flowchart on page 179 and the `PLANOT` listing, which begins at line 474 of the Utility Plotting Program listing on page 165.

Increasing Your Plotting Skills

The Utility Plotting Program has numerous applications. Enhancements to these applications are also possible through the programs listed on pages 167 and 168, as well as through other programs you may wish to write. The material in this section can help you get started. However, one of the best ways to learn how to get the most performance from the Utility Plotting Program is to experiment with various combinations of parameters in the plotting data base. This will help you to gain deeper insights into how these parameters control plotting and, if you use the plotter module regularly, to develop an intuitive knowledge of the parameters needed to control any plotting situation.

This is the end of part I. If you wish to learn how the individual plotter module functions operate, turn to part II. If you wish to generate bar code either on your plotter or on the HP 82162A Thermal Printer, turn to section 7, Bar Code, which begins on page 108.

Introduction

This section explains plotting boundary and scale concepts, and describes the plotter module functions you can use to implement these concepts.

Graphic Limits

A plotter has physically imposed limitations that restrict the region in which it can plot. For example, the HP 7470A Plotter is limited by the pen-carriage and paper transport mechanisms. Because of these physical limitations, the plotter module defines limits that restrict plotter operations. All pen movement is restricted to the area inside these *graphic limits*—sometimes called the “hard-clip” area.

Whenever a plotter is initialized, such as when it's turned on, it sets its graphic limits to its internal default values and stores these values internally. (Refer to the owner's manual for your plotter to determine its graphic limits.)

You can decrease (or slightly increase) the default graphic limits. This enables you to change the margin around the entire plot. You can change the graphic limits in two ways:

- Using the plotter module, as described in this section.
- Using the plotter's keyboard. This requires moving the pen to the lower left corner point P1 and pressing the appropriate keys (refer to your plotter owner's manual), then moving the pen to the upper right corner point P2 and again pressing the plotter keys. The points P1 and P2 define the graphic limits and a rectangular graphic area within.

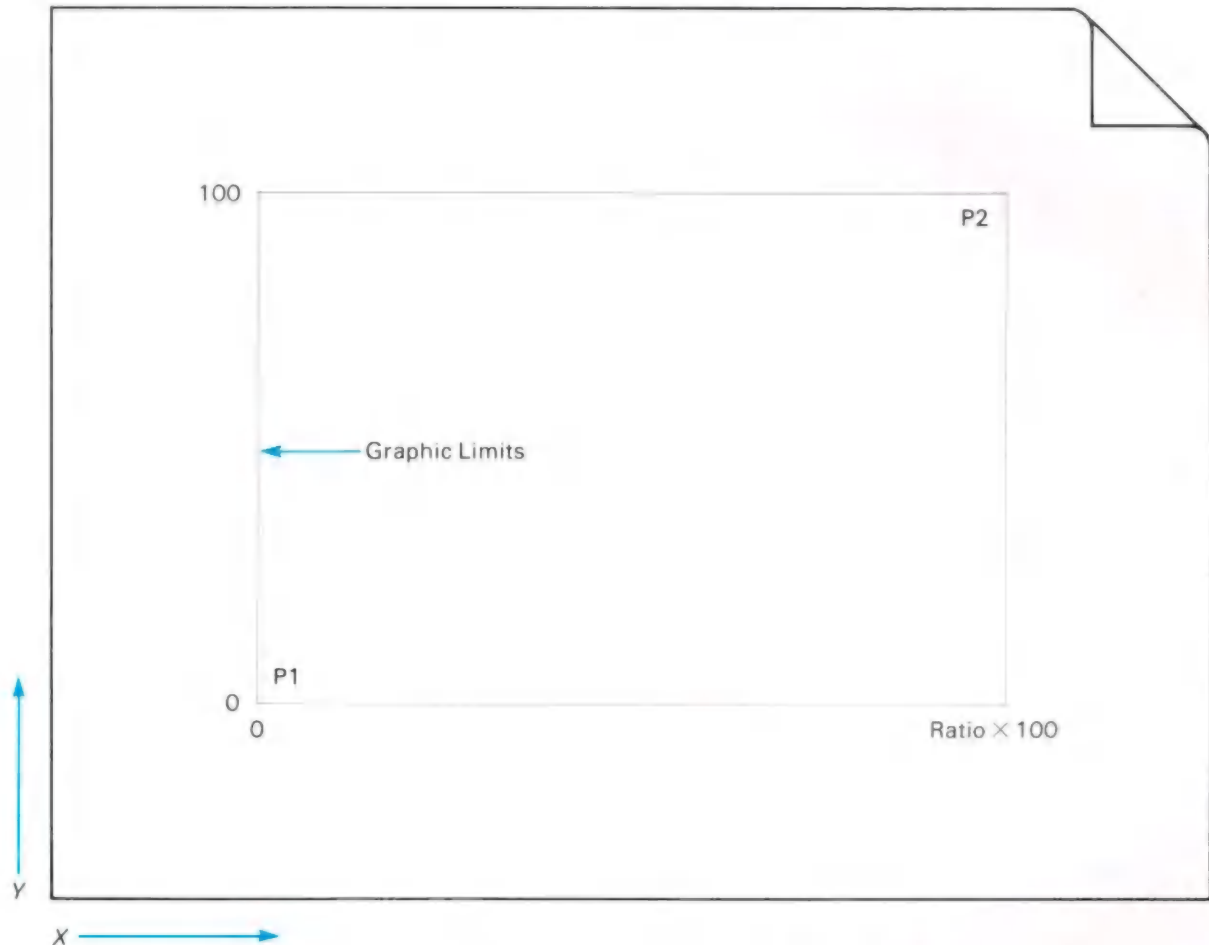

The revised limits are stored internally by the plotter.

Graphic Scale and GUs

Each point within the graphic limits can be represented by a pair of coordinates relative to the lower-left corner of this area. The *graphic scale* determines how such coordinates are measured within the graphic limits—it determines units with which you can measure distances.

The graphic area is characterized in terms of two dimensions: the x -dimension (horizontal) and the y -dimension (vertical). These dimensions are measured relative to the lower-left corner, which has the coordinates (0,0).

Regardless of the size of the graphic area, the shorter dimension is always scaled from 0 to 100 units. This dimension may be the x dimension or the y dimension, depending upon the shape of the graphic area. The longer dimension is scaled using units of the same size—naturally, there are more units along the longer dimension.

These units, used to scale the graphic area, are called *graphic units*, or simply GUs. GUs are useful for locating points using a percentage basis, since there are always 100 GUs in one dimension.

The ratio R is defined for the graphic area as the number of units in the x -dimension divided by the number of units in the y -dimension. This ratio, which can be computed using the plotter module, is helpful for finding the longer dimension of the graphic area.

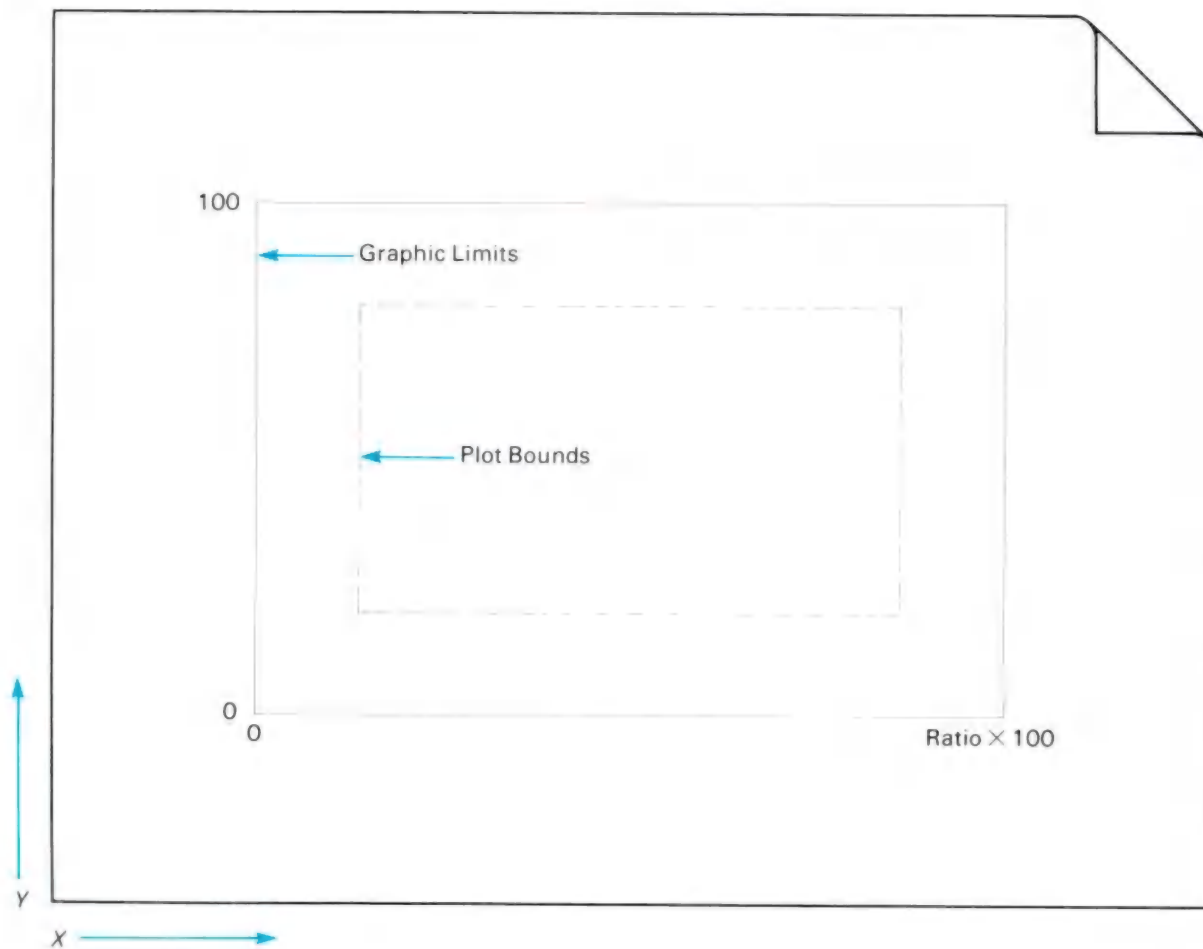

If the Longer Dimension Is	Then the Ratio Is	And the X-Dimension Is	And the Y-Dimension Is
$x > y$	$R > 1$	$100 \cdot R$	100
$y > x$	$R < 1$	100	$100/R$
$x = y$	$R = 1$	100	100

For example, the graphic limits of the HP 7470A Plotter are 0 to 138.8888 GUs in the x -direction and 0 to 100 GUs in the y -direction when the plotter is first turned on. Thus, R is equal to 1.3888. You can specify any valid point using x and y coordinates within these ranges. Of course, if you redefine the graphic limits, both the ratio and the number of GUs along each axis may change.

Plot Bounds

The constraints imposed by the graphic limits can be further restricted for plotting operations. This enables you to reserve space within the graphic area for labels, for example.

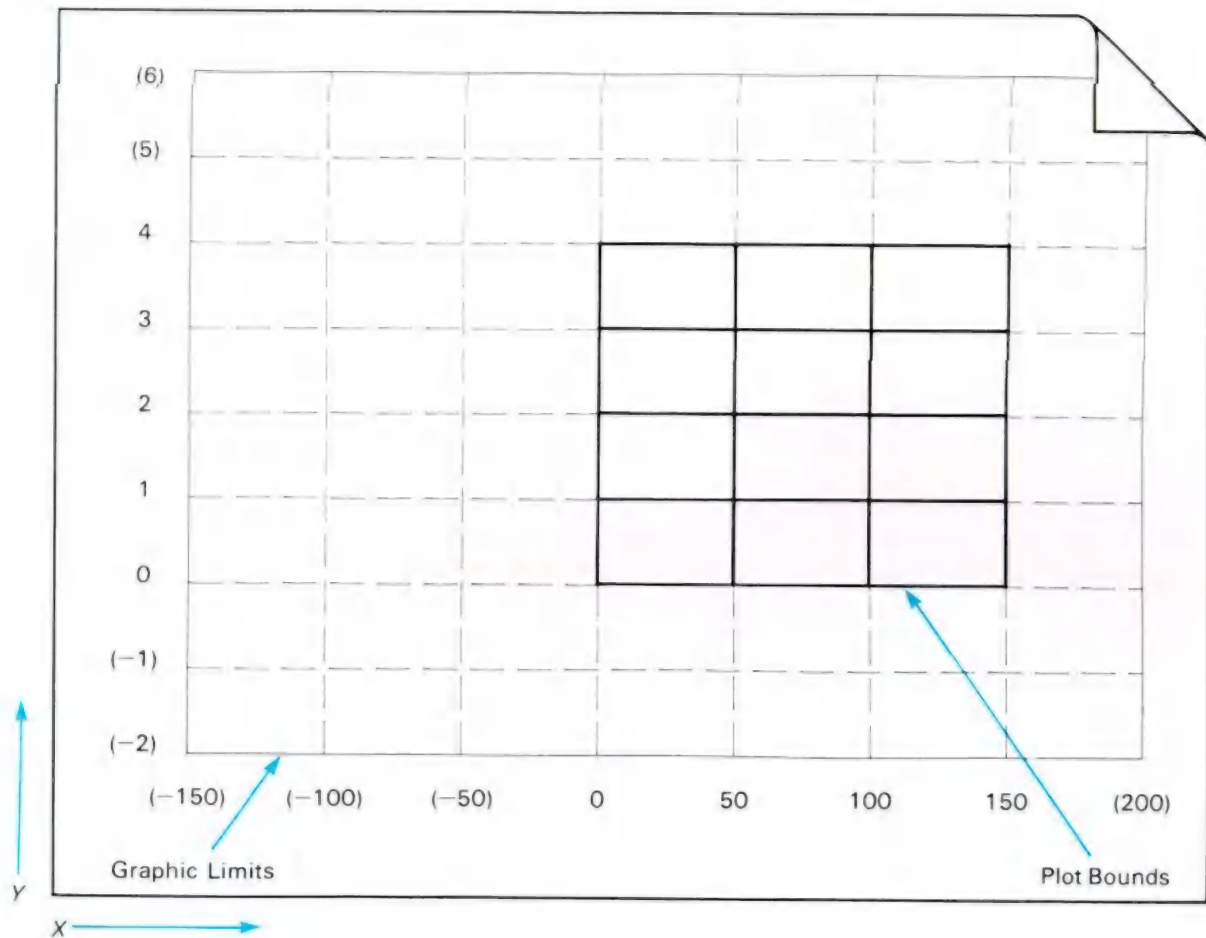

You can use the *plot bounds* to define a rectangular area that represents the usable plotting area—sometimes called the “window” or the “soft-clip” area. This area is intended for plotting, such as drawing lines and axes. The pen can move outside the plot bounds only for operations such as writing labels. (The HP-41 can never move the pen outside the graphic limits.)

User Scale and UUs

You can create your own units of measure that apply to the area inside the plot bounds. This enables you to scale this area using units that are appropriate for the values being plotted. For example, if you're plotting height versus weight, you might define the vertical scale of the plot bounds to be 0 to 4 (meters) and the horizontal scale to be 0 to 150 (kilograms).

The units that define the *user scale* are called *user units*, or UUs. Although you can't use the user scale to plot outside the plot bounds, the user scale does extend to the graphic limits, enabling you to specify label positions. If you don't define UUs for the plotting area, they remain equal to the range of GUs that fall within the plot bounds.

The UUs defined for the plot area remain in effect even if you change the plot bounds. In effect, the user scale remains the same over the entire graphic area—only the plot bounds shift. However, you can redefine the user scale for the new bounds.

GU Mode and UU Mode

Although you may have defined plot bounds, the use of those plot bounds is optional. You can still choose to plot and label anywhere within the graphic limits instead. Note that the plot bounds may coincide with the graphic limits, such as when you redefine the graphic limits. The plot bounds will never be outside the graphic limits.

GU mode is the operating mode in which you can access the entire area inside the graphic limits. Points are located using GUs.

UU mode is the operating mode in which you normally access only the area inside the plot bounds. Points are located using UUs. This is the mode that the plotter module starts in when it's initialized, as discussed in the next topic.

You can switch between GU mode and UU mode whenever you want to. This enables you to move the pen anywhere within the graphic limits (using GUs) or to limit pen movement (except for labeling) to within the plot bounds (using UUs).

Five functions in the plotter module automatically set the plotting mode. (These functions are described later in this section.) The table below shows how the plotting mode is affected by these functions.

Function	Sets UU Mode	Sets GU Mode
<code>PINIT</code>	X	
<code>LIMIT</code>	X	
<code>SCALE</code>	X	
<code>SETUU</code>	X	
<code>SETGU</code>		X

The last two functions in the preceding table affect only the plotting mode. They enable you to select the mode that is most useful for the operation being performed.

`SETGU`

The `SETGU` (*set GU mode*) function switches the plotter module to GU mode. `SETGU` is useful when you want to move the pen outside of the plot bounds or when you want to control pen movement using the GU scale instead of the UU scale.

`SETUU`

The `SETUU` (*set UU mode*) function switches the plotter module to UU mode. `SETUU` is useful when you want to restrict most pen movement to within the plot bounds and when you want to control pen movement using the UU scale instead of the GU scale.

When the plot bounds and the graphic limits are the same and their respective scales are equal, executing `SETGU` or `SETUU` has no effect on plotting operations.

The following functions (described in later sections) operate and interpret parameters according to the current mode—either GU mode or UU mode.

<code>DGTIZE</code>	<code>IPLLOT</code>	<code>PLOT</code>	<code>XAXIS</code>
<code>DRAW</code>	<code>LXAXIS</code>	<code>PLREGX</code>	<code>XAXISO</code>
<code>FRAME</code>	<code>LYAXIS</code>	<code>RPLLOT</code>	<code>YAXIS</code>
<code>IDRAW</code>	<code>MOVE</code>	<code>WHERE</code>	<code>YAXISO</code>
<code>IMOVE</code>			

Initializing and Clearing the I/O Buffer

As described under Memory Requirements and the I/O Buffer, page 10, the plotter module maintains an I/O (input/output) buffer in HP-41 memory. This buffer stores information used for plotting.

`PINIT`

The `PINIT` (*plotter initialize*) function reserves 26 unused memory registers for the I/O buffer if it does not already exist, and initializes the I/O buffer. If the I/O buffer does not exist, you must create it, by executing `PINIT` once, before you execute most other plotter module functions. (If the I/O buffer does not exist when needed, the HP-41 displays **PL:PLS PINIT.**)

Whenever you turn on the plotter, it stores default graphic limits in its internal memory. (If new limits are defined, these are stored instead of the default limits.) `PINIT` reads the graphic limits from the plotter's memory—either its default values or other values stored there by previous operations—and stores them in the I/O buffer.

In addition, **PINIT** sets the following default conditions (which are described in more detail in later sections of this manual):

- Sets the plot bounds equal to the graphic limits.
- Sets UUs equal to GUs and sets the HP-41 to UU mode.
- Selects pen 1.
- Sets the line type to type 1.
- Sets the character space height to 3 GUs.
- Sets the label origin to position 1 and the label direction to 0°.
- Sets your plotter's default tic length for the x- and y-axes.
- Sets the plotting rotation to 0°.
- Sets the parameters for plotting bar code to their default values if the buffer is being created (that is, if it did not already exist when **PINIT** was executed)—otherwise, the parameters are not changed.

Thus, executing **PINIT** alone does not affect the graphic limits, but does reset other plotting parameters to their default conditions.

Because the I/O buffer uses 26 memory registers, if the buffer does not exist when you execute **PINIT** and there are less than 26 unused registers available, the HP-41 displays **PL:NO ROOM**. If this occurs, refer to Ensuring that Enough Unused Registers Are Available, page 11.

The 26 registers reserved by **PINIT** and used by the plotter module can be returned to program memory by executing the following function.

PCLBUF

The **PCLBUF** (*clear plotter buffer*) function clears the I/O buffer, returning the 26 memory registers used by the buffer to available program memory.

(Additional information about the I/O buffer is provided in section 8, Plotting Conditions and the Input/Output Buffer.)

Specifying the Graphic Limits

You can change the graphic limits at any time using the **LIMIT** function. This enables you to work with several successive graphic areas on a single sheet or to use differently sized areas on successive sheets.

LIMIT

T	x-minimum (mm)
Z	x-maximum (mm)
Y	y-minimum (mm)
X	y-maximum (mm)

The **LIMIT** function replaces the current graphic limits with the graphic limits specified in the X-, Y-, Z-, and T-registers. (The limits maintained by the plotter—P1 and P2—and those in the I/O buffer are changed.) In addition, **LIMIT** sets the default conditions listed above for **PINIT**—except that bar code parameters aren't changed.

The HP-41 always interprets **LIMIT** parameters as millimeters, measured from the origin point (0, 0) at the lower-left physical limit of the plotter. The **LIMIT** parameters should be within the physical limits of the plotter since the plotter can't move outside its physical limits. For example, the physical limits for the

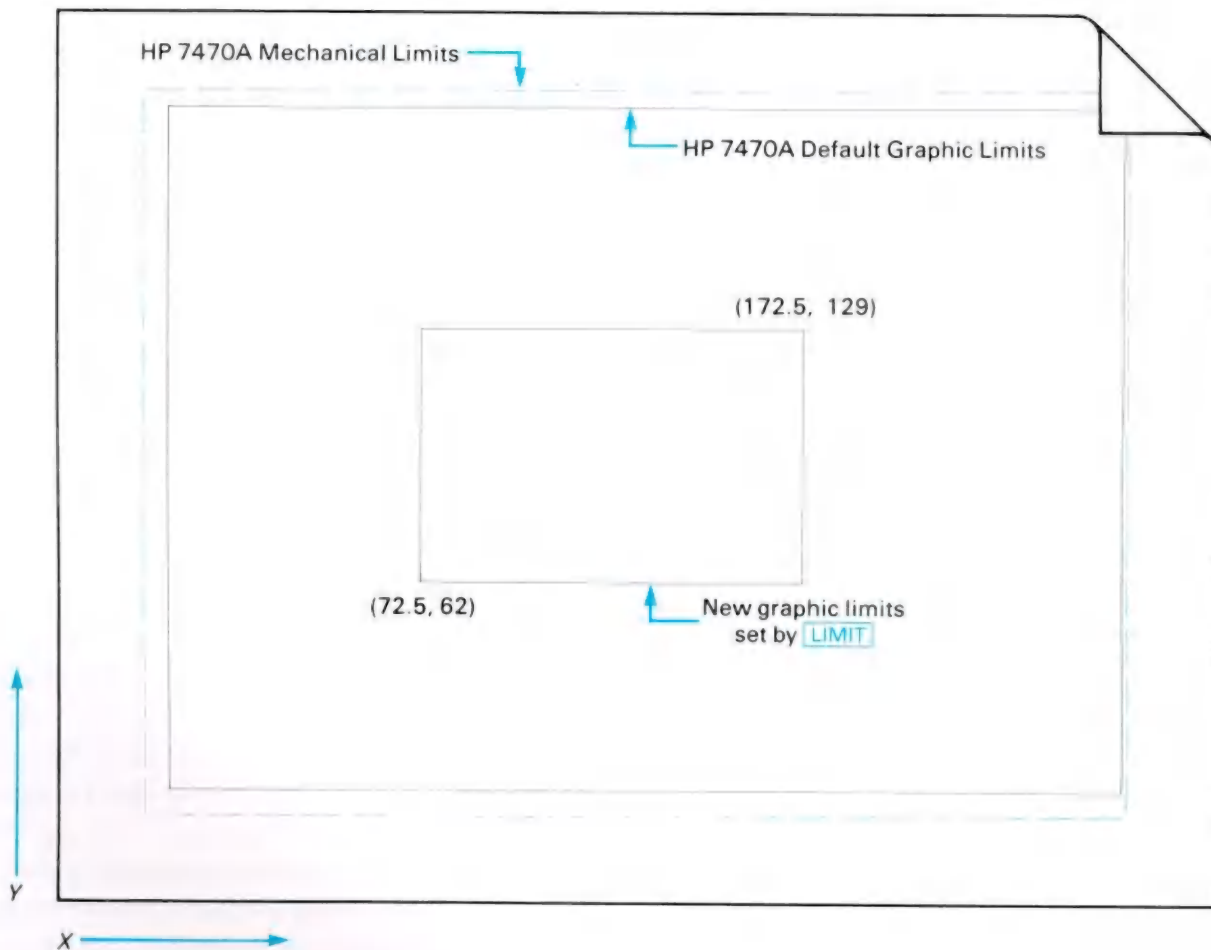

HP 7470A Plotter are 257.5 mm in the x direction and 191.25 mm in the y direction for "US" paper (272.5 mm \times 191.25 mm for "A4" paper). When the HP 7470A Plotter is first turned on, the graphic limits stored internally are slightly less than the physical limits (6 to 256 mm in the x direction and 7 to 187 mm in the y direction.)

Once **LIMIT** specifies the graphic limits, these limits do not change unless you perform one of the following operations:

- Execute **LIMIT** with a new set of parameters.
- Manually set new limits using the plotter's keys, then execute **PINIT**.
- Turn the plotter off, then on, and execute **PINIT**.

Note: When the plotter has been turned off, then on, its internal limit points are reset to their default values. The next execution of **PINIT** resets the graphic limits maintained in the I/O buffer to the plotter's default values.

Example: Specify graphic limits having a 100-millimeter x -dimension, a 67-millimeter y -dimension, and a lower-left corner positioned 72.5 millimeters to the right of, and 62 millimeters above, the (0,0) mechanical limit of your plotter. Then use the **FRAME** function (discussed in section 4) to plot a frame, or outline, at the new graphic limits.

Keystrokes	Display	
PINIT		Initializes the buffer. (If the I/O buffer does not already exist, requires 26 unused memory registers.)
72.5 ENTER \uparrow	72.5000	Enters x -minimum.
172.5 ENTER \uparrow	172.5000	Enters x -maximum.
62 ENTER \uparrow	62.0000	Enters y -minimum.
129	129 _	Enters y -maximum.
LIMIT	129.0000	Sets the new graphic limits.
FRAME	129.0000	Frames the new graphic limits.

The frame drawn by your plotter should look like the one shown in the preceding illustration. (These new graphic limits are used in the next example.)

If you reverse the positions of x -minimum and x -maximum or y -minimum and y -maximum in the stack, **LIMIT** defines the corresponding graphic and user scales in the reverse direction (right-to-left or top-to-bottom).

RATIO

The **RATIO** function calculates the x -to- y ratio R —truncated to four decimal places—of the area within the graphic limits and enters the ratio into the X -register. That is, the ratio is equal to the number of units in the x -dimension divided by the number of units in the y -dimension. (You can work with either millimeters or GUs when calculating the ratio R .)

RATIO can be used find the length in GUs of the long side of the graphic limits. For instance, **RATIO** returns a value of $R = 1.3888$ (or 250 mm/180 mm) when the module is used with an HP 7470A Plotter set to its default limits. Thus, the maximum x -value (the longer dimension) for these limits is $100 \times R$, or 138.88 GUs. Remember that the length of the shorter side is always equal to 100 GUs. (Refer to the chart on page 65.)

Example: Find the ratio for the graphic limits set in the previous example and compute the length of the longer side in GUs. In this case, the longer side of the plotting area is the x side. Because the shorter side is always equal to 100 GUs, the length (in GUs) of the x -dimension is $100 \times R$. (The following keystrokes assume that the graphic limits defined in the previous example remain in memory.)

Keystrokes	Display	
RATIO	1.4925	The ratio of the x -dimension to the y -dimension.
100 X	149.2500	The length, in GUs, of the x -dimension.

RATIO can be particularly useful in determining the length of the longer side after you manually set the graphic limits using the plotter's keyboard.

Setting the User Scale

When the HP-41 is initialized for plotting by **PINIT**, the HP-41 is set to UU mode and the plot bounds define the current plotting area. (The plot bounds are set by **PINIT** and **LIMIT** and can be revised by several functions discussed under the next heading.) The user scale, which is associated with the plot bounds, is initially set to be the same as the graphic scale that lies within the plot bounds.

Often you want a user scale (UUs) that is more convenient than the graphic scale (GUs). The **SCALE** function enables you to define a user scale that is appropriate for your application.

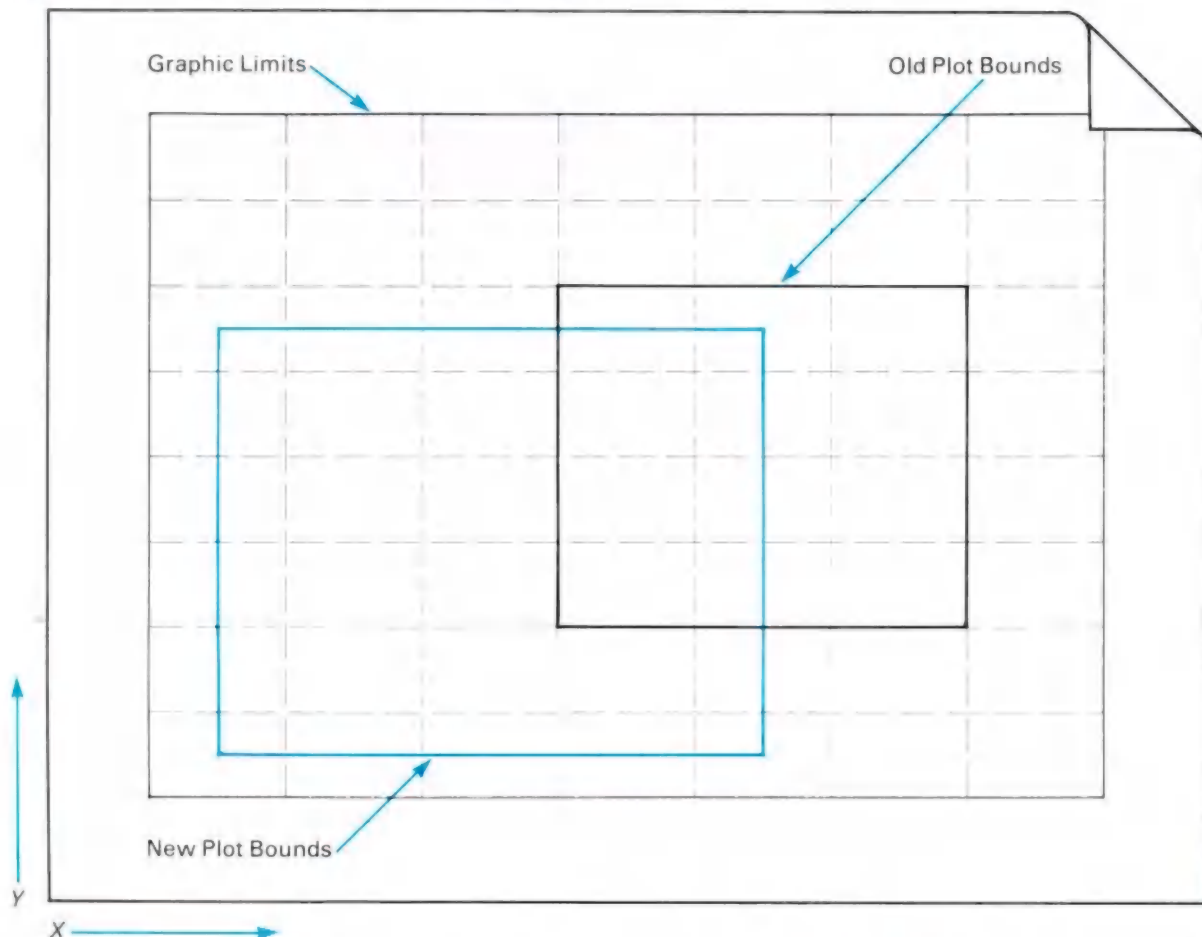

SCALE

T	x-minimum (UUs)
Z	x-maximum (UUs)
Y	y-minimum (UUs)
X	y-maximum (UUs)

The **SCALE** function sets the user scale from the x- and y-dimensions of the plot bounds and sets the plotter module to UU mode. The scaling for the x- and y-directions are independent of each other. Thus, plots are stretched or shrunk independently in the x- and y-directions to fit the plotting area. (This is sometimes called “anisotropic scaling.”)

SCALE is particularly convenient for plots where the lengths of the x- and y-units differ. In the program for the annual rainfall plot (page 15), **SCALE** is used to specify years on the x-axis and inches on the y-axis. (Refer to program lines 33 through 40 in the listing of this program on page 161).

Although the user scale is defined by the x and y values at the plot bounds, the scale extends to the graphic limits—primarily for locating labels. If the plot bounds—but not the graphic limits—are subsequently revised (using functions described in the next topic), the user scale remains unchanged; the portion of the scale inside the new plot bounds becomes the usable plotting scale. Of course, you can use **SCALE** to define a new user scale for the new plot bounds.

The user scale—whether the default user scale or a scale you set using **SCALE**—remains in memory until it is cleared by one of the following operations:

- You execute **SCALE** to specify another user scale.
- You execute **PINIT** or **LIMIT**, which resets the graphic limits, plot bounds, and scales.

Note: Using the plotter keys to change P1 and P2 does not change the scale, but does affect the results of some plotting operations. Thus, if you use the plotter keys to change P1 and P2, it is recommended that you then reinitialize the I/O buffer by executing **PINIT**.

If the x or y parameters are reversed in the stack registers, the corresponding scale will be inverted relative to the normal left-to-right or bottom-to-top direction.

An example that uses **SCALE** is included in the next topic, which discusses revising (and scaling) the plot bounds.

Revising the Plot Bounds

Whenever you create new graphic limits (by using **PINIT** or **LIMIT**), the plot bounds are set equal to the new limits. The plotter module provides you with three functions you can use for revising the plot bounds, enabling you to specify plot bounds anywhere within the graphic limits.

The first function, **LOCATE**, uses GUs to define the bounds (that is, it uses the graphic scale). The second function, **CLIPUU**, uses UUs to define the bounds (that is, it uses the user scale). Note that the graphic and user scales may be the same, as they are after **PINIT** or **LIMIT** is executed; or the scales may be different, as they would be if you defined a user scale (using **SCALE**). The third function, **UNCLIP**, sets the plot bounds at the graphic limits. These functions are described below.

LOCATE is often used to establish plot bounds *prior* to specifying a user scale, while **CLIPUU** is often used to establish plot bounds *after* a user scale has been defined using the **SCALE** function.

There are many uses for specially-sized plot bounds. Two of the most frequent uses are to allow space outside of a plot for labeling or to create a window effect to show only part of a plot.

LOCATE

T	x-minimum (GUs)
Z	x-maximum (GUs)
Y	y-minimum (GUs)
X	y-maximum (GUs)

The **LOCATE** (*locate plot bounds*) function allows you to specify plot bounds that are anywhere within the graphic limits. The **LOCATE** parameters are interpreted as GUs. **LOCATE** does not change the user scale and can be executed while the plotter is in either UU mode or GU mode.

Example: Define graphic limits that are from 0 to 246 millimeters in the x-direction and from 16 to 184 millimeters in the y-direction. (The GU scale for these graphic limits is 146.2 GUs in the x-direction and 100 GUs in the y-direction.) Then define the plot bounds to be 100 GUs by 80 GUs and centered within the graphic limits.

CLIPUU

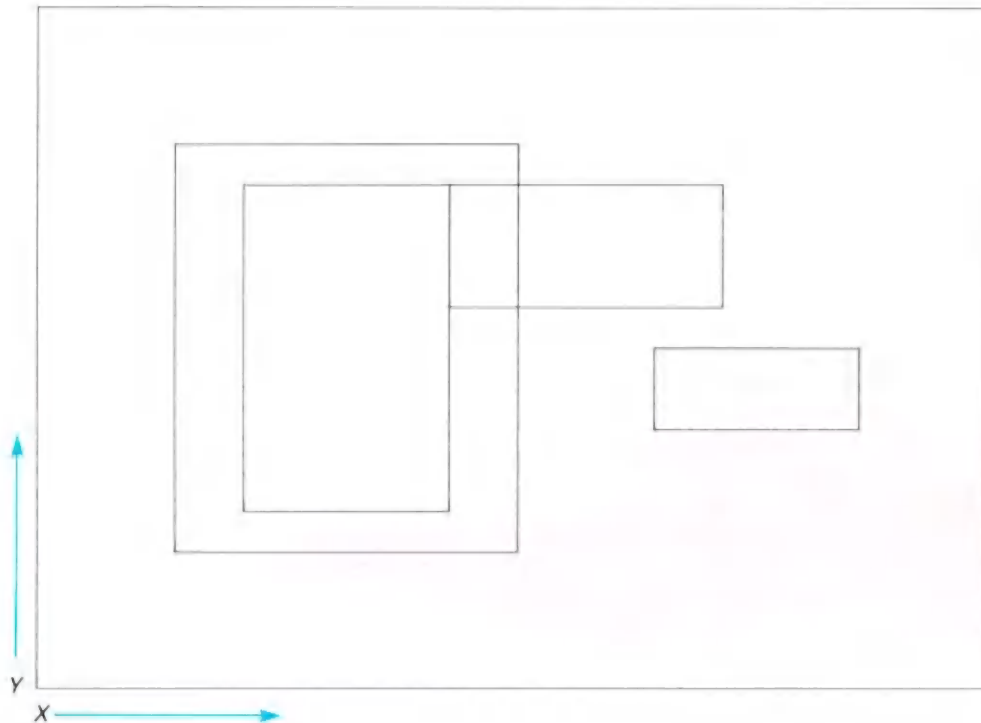

T	<i>x</i> -minimum (UUs)
Z	<i>x</i> -maximum (UUs)
Y	<i>y</i> -minimum (UUs)
X	<i>y</i> -maximum (UUs)

The **CLIPUU** (*clip-UUs*) function operates in the same way as the **LOCATE** function except that the parameters are interpreted as UUs—whether or not the HP-41 is currently set to UU mode.

UNCLIP

The **UNCLIP** function resets the plot bounds to match the graphic limits—the largest plot bounds possible without redefining the graphic limits. The user scale is not changed.

Example: Set the graphic limits to the default values by turning the plotter off and on, then executing **PINIT**. Use **LOCATE** and **SCALE** to create plot bounds and scale them. Then use **CLIPUU** to create various new plot bounds using the user scale. Finally reset the plot bounds to the graphic limits.

GCLEAR

The **GCLEAR** (*graphics clear*) advances the page on plotters that have page feed mechanisms. **GCLEAR** has no effect on the operation of a plotter that does not have a page feed—such as the HP 7470A Plotter.

Saving Steps

The subroutines under the following two headings are designed to save you time by providing a standardized setup and termination for many of the examples in this manual. You may want to design similar subroutines to keep available in program memory for use in your plotting applications.

Initializing the HP-41 for Examples

Most of the remaining examples in this manual assume that the HP-41 is initialized to the plotting conditions set by the following SET program. To ensure that the desired conditions are active, these examples include execution of SET. To save you time and to help focus your attention on the functions illustrated in the examples, enter this program into your HP-41 now so that you can easily execute it when needed to set up your plotting system. (Bar code for SET is on page 205.)

Following execution of SET, the HP-41 is in UU mode with **FIX** 0 display and Degrees mode.

*As indicated in the discussion of **PINIT** on page 68, **PINIT** uses the graphic limits to which your plotter is currently set. Also, if the I/O buffer does not already exist when you execute SET, 26 unused memory registers must be available for **PINIT** to use for creating the buffer.

Terminating Examples

After you complete an example, you will usually want the plotter to display your work, return the pen to its stall, and return plotting parameters to their default values. The following TERM (for "termination") program performs these steps. Like the SET program, TERM is called as a subroutine by several of the program examples listed elsewhere in this manual. (Bar code for TERM is on page 205.)

Framing the Plotting Area

`FRAME`

The `FRAME` function draws a box around the active plotting area. That is, if GU mode is active, `FRAME` draws a box at the graphic limits. If UU mode is active, `FRAME` draws a box at the plot bounds.

Moving the Pen and Drawing Lines

The following four functions control the basic operations of moving the pen—with or without drawing a line. They automatically ensure that the pen is “down” or “up” according to the operation you specify.

Moving and Drawing to a Point

`MOVE`

Y	<code>y-coordinate (UUs or GUs)</code>
X	<code>x-coordinate (UUs or GUs)</code>

The `MOVE` function moves the pen to the specified (x,y) coordinate position without drawing a line. The coordinates are interpreted as the current units—either UUs or GUs. In UU mode the pen moves only within the plot bounds. In GU mode the pen moves anywhere within the graphic limits.

`DRAW`

Y	<code>y-coordinate (UUs or GUs)</code>
X	<code>x-coordinate (UUs or GUs)</code>

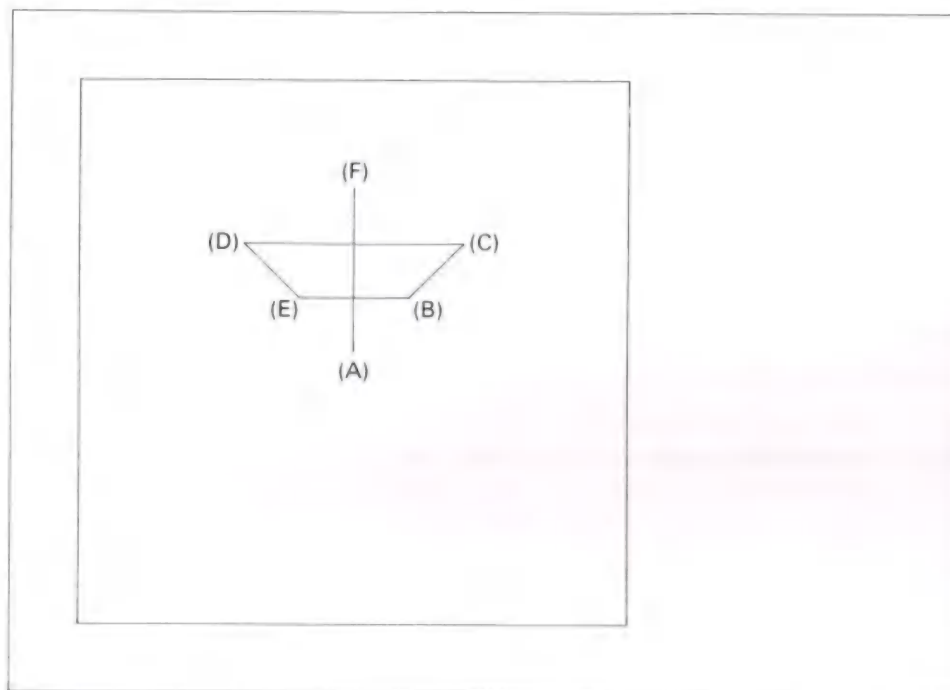

The `DRAW` function draws a line from the current pen position to the specified (x,y) coordinate position, then lifts the pen. The coordinates are interpreted as the current units—either UUs or GUs. The line type conforms to the current line type and repeat interval. When UU mode is active, you can draw lines only within the plot bounds. When GU mode is active, you can draw lines anywhere in the graphic limits.

Moving and Drawing by Increments

IMOVEY **y-increment (UUs or GUs)**X **x-increment (UUs or GUs)****IDRAW**Y **y-increment (UUs or GUs)**X **x-increment (UUs or GUs)**

The **IMOVE** (*incremental move*) and **IDRAW** (*incremental draw*) functions operate in the same way as **MOVE** and **DRAW** except that pen travel is specified by x- and y-increments. The origin—point (0,0)—is assumed to be the most recent pen position. The direction of incremental pen travel can be rotated using **PDIR**. (Refer to Rotating the Plot Axes, page 86.)

Example: Use **IMOVE** and **IDRAW** to plot the following simple diagram where, after you initially position the pen, the coordinates of each pen movement are expressed in increments from the most recently specified pen position.

<code>ALPHA</code>	0.0000	

In the preceding examples you have seen how the pen operates *inside* the plotting area. Before continuing with pen control functions, let's discuss pen movement to or from points *outside* the plotting area.

Moving and Drawing Outside the Plotting Area

The plotter module controls pen travel during “move” and “draw” operations so that it remains within the current plotting area—the graphic limits in GU mode or the plot bounds in UU mode. If you specify points that lie outside the plotting area, pen travel accurately reflects the portion of the intended travel that falls within the plotting area.

For example, if you execute a “move” or “draw” function using coordinates that are outside the plotting area, the pen travels to the point at the edge of the area in the direction of the point, but halts when it reaches the edge. If you then execute a “move” or “draw” function to a point within the plotting area, the pen first travels to the appropriate point at the edge where the line from the distant point to the new point should reenter the plotting area, then travels to the new point. If both points are outside the plotting area, the pen travels only on the portion of the line that lies within the plotting area.

If you use the HP-41 to specify a point outside the plotting area, repositioning the pen using the plotter's keyboard does not change the pen position maintained in the I/O buffer. That is, if you reposition the pen using the plotter's keyboard, then execute a “move” or “draw” function, the pen returns to the last position you specified using the HP-41, then executes the function.

Using Plot-Option Functions

There are four plot-option functions: `PLOT`, `IPLOT`, `RPLLOT`, and `PLREGX`. These functions draw a line or simply move the pen according to the current line type and pen status.

Pen Status

The plotter module maintains an internal pen status to control the pen's “up” or “down” position during periods of pen activity. For the pen movement functions described previously, you need not be concerned with the current pen status—these functions automatically change the pen status as required.

If the pen is “down” when pen activity halts, the module temporarily lifts the pen to prevent the ink from blotting the paper—but doesn't change the internal pen status from “down.” When pen activity resumes, the module reinstates the “down” status. (That is, the pen is lowered.)

The four plot-option functions described on the following pages use the pen status remaining from the preceding operation to determine whether to draw a line or to simply move the pen to the next point. If you use these functions, you will want to know how functions affect the pen status.

The following functions set the pen status to “down”:

<code>PENDN</code>	<code>PLOT</code>	<code>RPLOT</code>
<code>DRAW</code>	<code>IPLOT</code>	<code>PLREGX</code>
<code>IDRAW</code>		

All other functions that use the pen set the pen status to “up.” `PINIT` sets the pen status to “up.” Other functions that do not cause pen movement, such as `SCALE` and `RATIO`, are neutral. (A pen status indicator is maintained in the I/O buffer—refer to section 8.)

The pen status remaining from the last pen movement command affects the way the plotter responds to a new plot-option command:

- If the pen status is “down,” the plotter draws a line to the specified point(s) and halts. The pen status remains “down” (although the pen is lifted to prevent blotting).
- If the pen status is “up,” the plotter moves the pen to the specified point without drawing a line, sets the pen status to “down,” and drops the pen (although the pen is lifted again to prevent blotting).

If the plot-option function is `PLREGX`, a series of points can be connected (that is, several lines drawn) with one execution of the function. If the pen status is “up” when `PLREGX` is executed, no line is drawn when the pen moves to the first point in the series—but at that point the pen status is set to “down.”

The Plot-Option Functions

The four plot-option functions share these common properties:

- They define the specified position using current units—either UUs or GUs.
- They move the pen from its present position to the specified position using the existing pen status—“up” or “down.”
- They set the pen status to “down” when they reach the point—except as provided by `PLREGX`.
- They move the pen only within the current plotting area—either the plot bounds (in UU mode) or the graphic limits (in GU mode).

The functions differ in the ways that they specify the points and the number of points that can be specified.

<code>PLOT</code>	Y <code>y-coordinate (UUs or GUs)</code>
	X <code>x-coordinate (UUs or GUs)</code>

When you execute `PLOT`, the pen moves or draws to the actual (x,y) coordinate position.

<code>IPLOT</code>	Y <code>y-increment (UUs or GUs)</code>
	X <code>x-increment (UUs or GUs)</code>

The `IPLOT` (*incremental plot*) function specifies pen movement by x- and y-increments. The origin (both increments 0) is the current pen position—the origin changes every time the pen moves.

The direction of incremental pen movement can be rotated using **PDIR** (page 86).

RPLOTY **y-relative (UUs or GUs)**X **x-relative (UUs or GUs)**

The **RPLOT** (*relative plot*) function specifies a point using its position relative to an assumed origin. The assumed origin is the last position determined by a function other than **RPLOT**—that is, **RPLOT** *doesn't* change the assumed origin, but any other pen movement *does* change the origin.

The direction of a relative pen movement can be rotated using **PDIR** (page 86).

Example of Absolute, Incremental, and Relative Plotting. Draw a diamond shape in each of three corners of the plot bounds using **PLOT**, **IPLOT**, and **RPLOT**.

Save this plot for the next example.

**PLREGX**X **iii.fff**

R_{iii}	x_1 (UUs or GUs)
\vdots	
R_{fff}	y_n (UUs or GUs)

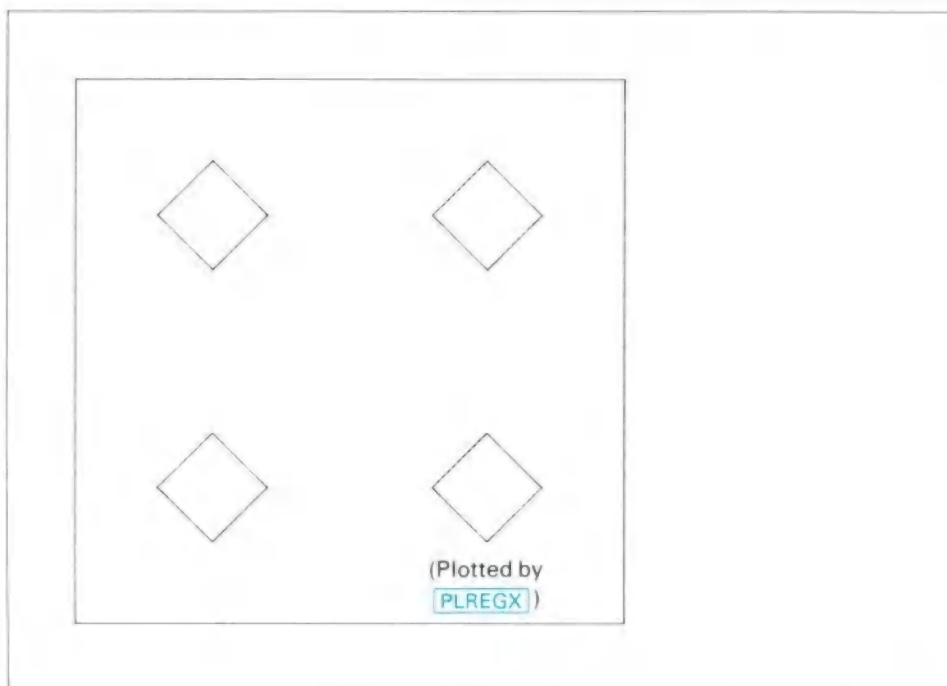

The **PLREGX** (plot registers according to X) function enables you to plot several lines (x, y coordinate pairs) from data you have previously stored in a series of data storage registers. This allows the plotting to be performed relatively fast since only one plotting function is performed. Coordinates are interpreted as current units—either UUs or GUs.

You specify the series of registers by placing in the X-register a number in the form **iii.fff**, where **iii** indicates the initial register and **fff** indicates the final register. **PLREGX** interprets the values in the first and second registers of the series (R_{iii} and R_{iii+1}) as the x - and y -coordinates of the first point (P_1) of your plot. The values in the third and fourth registers of the series are interpreted as the x - and y -coordinates of the second point (P_2), and so on.

Diamond Example Continued. Use **PLREGX** to draw a diamond shape in the unused corner of the plot remaining from the preceding example. Use the data storage registers shown below.

R_{00}	75	x_1	} Identifies first point.
R_{01}	15	y_1	
R_{02}	85	x_2	} Identifies second point.
R_{03}	25	y_2	
R_{04}	75	x_3	} Identifies third point.
R_{05}	35	y_3	
R_{06}	65	x_4	} Identifies fourth point.
R_{07}	25	y_4	
R_{08}	75	x_1	} Identifies first point (closes diamond).
R_{09}	15	y_1

25 ENTER 75 MOVE	75.	Moves pen to center point of fourth diamond (25, 75) and sets pen status to "up."
.009 PLREGX	9. -03	Specifies R ₀₀ through R ₀₉ as registers containing coordinates of points to plot. Pen moves to first point, then sets pen status to "down" for remaining points.
XEQ ALPHA TERM ALPHA	0.0000	Terminates example. (Refer to Terminating Examples, page 77.)

If the pen status is set to "up" when **PLREGX** is executed, the pen moves to the first point, changes the pen status to "down," and begins plotting. If the pen status is set to "down" when **PLREGX** is executed, the pen status remains "down"—it draws a line from its current position to the first point, then plots the specified points. In other words, as soon as the pen moves to the first point, **PLREGX** sets and leaves the pen status as "down."

However, **PLREGX** provides a method for lifting the pen between points. If an Alpha string occupies either register representing a coordinate pair, that coordinate pair is ignored and the pen lifts—although the

internal pen status remains "down." The pen moves, in the "up" position, to the next point, then drops in preparation for plotting the next line. Note that an Alpha string causes the pen to move without drawing a line, but that the pen status remains "down."

Example: Draw a line from (0, 0) to (10, 20) to (20, 30) and a line from (30, 30) to (43, 35) to (60, 70). Use the storage registers shown below.

R ₀₁	0	x ₁	}	First point.

 Specifies R_{01} through R_{14} .
 Plots lines without connecting points 3 and 4.

 Terminates example. (Refer to Terminating Examples, page 77.)

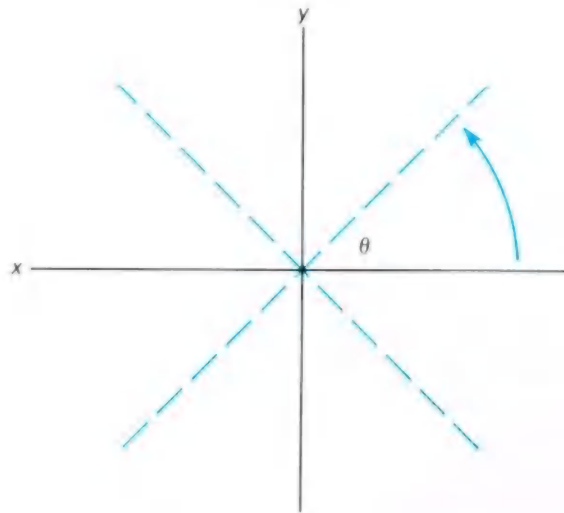

For another application of `PLREGX`, refer to the RAIN Program listed on pages 160 and 161. Lines 06 through 21 use a loop for programmed data input. The `PLREGX` function in line 84 of that program uses the input at line 83 for the necessary *iii.fff* number.

Rotating the Plot Axes

`PDIR`

 X `angle`

The `PDIR` (*plot direction*) function rotates the x - and y -axes to the specified angle and sets the new direction for incremental plotting (`IMOVE`, `IDRAW`, and `IPLT`) and relative plotting (`RPLT`) only. `PDIR` does not affect pen movement specified by absolute coordinates. The angle is specified as positive in the counterclockwise direction and is interpreted according to the HP-41's current angular mode (`DEG`, `RAD`, or `GRAD`).

The angles of all successive **PDIR** functions refer to the original, unrotated axes, not to a previously rotated pair of axes. The default angle (set by **PINIT** and **LIMIT**) is 0° .

Example: Use **PDIR** to plot the figure below.

Notice in this example that the assumed origin remained at (1, 1), the origin established by each **PLOT** function.

Other Pen Control Functions

The following functions enable you to control pen conditions and the type of line the pen draws. These functions give you flexibility for plotting lines of different styles and colors.

PEN

X **pen number**

The **PEN** (*pen*) function selects the pen indicated by the number in the X-register. When **PEN** is executed, the actual pen that is selected depends upon the capability of the plotter that you're using. For example, the HP 7470A Plotter selects its left pen for odd pen numbers and its right pen for even numbers. Other plotters have only one pen, which they always use regardless of the pen number. (Refer to your plotter owner's manual for information about pen selection.)

After the specified pen is retrieved, the pen returns to the position it occupied when **PEN** was executed.

If the pen number is 0, executing **PEN** returns the current pen to its stall (if the plotter has that capability). **PEN** uses the absolute value of the integer portion of the pen number.

Whenever you execute **PINIT** or **LIMIT**, the pen number is set to "1" and the plotter selects pen number 1.

PENDN

The **PENDN** (*pen down*) function lowers the pen to the plotting surface. The pen remains in contact with the surface until another function causes it to lift.

PENUP

The **PENUP** (*pen up*) function lifts the pen from the plotting surface.

LTYPE**X** *line type*

The **LTYPE** (*line type*) function uses a line type number (integer value 1 through 8) to select one of eight solid or dashed line types for drawing or plotting. A type number of 0 yields the same line as type 1. If you specify a number larger than 8, the current line type is not changed.

Whenever you execute **PINIT** or **LIMIT**, the line type is set to type 1 (a solid line).

Example: The following program illustrates the line types selected by the type numbers and generated by the plotter. (A bar code listing of this program begins on page 99.)

Introduction

The functions described in this section enable you to write titles or other labels on your plots, to draw axes and grids, and to label the axes. Using these functions, you can enhance your plots with important information presented in useful formats.

Using Labels

Labels can be drawn in almost any size, location, and rotation within the graphic limits, regardless of the active plotting mode—UU mode or GU mode.

Printing a Label

`LABEL`

ALPHA `alpha string`

The `LABEL` function prints the contents of the ALPHA register at the last pen position specified by the HP-41 and within the graphic limits. To use `LABEL`, first position the pen at the desired point, such as by executing one of the moving, drawing, or plot-option functions described in section 4. Then execute `LABEL`. (`LABEL` prints only at pen positions set by the HP-41; it ignores pen movement performed by the plotter's pen control keys.)

The `LABEL` function permits the pen to move outside the plot bounds in UU mode—although the pen can't move outside the graphic limits. This lets you print labels in the margin between the plot bounds and the graphic limits. However, you should note that when you position the pen prior to executing `LABEL`, it moves only as far as the plot bounds—the pen moves to the specified position when you execute `LABEL` (before the label is printed). The HP-41 remembers the actual point you specified for the label position. This ensures that the pen remains inside the plot bounds except for printing a label.

Example: Print labels that lie within and extend outside of the plot bounds.

Enters label.

Specifies pen movement to point outside plot bounds at lower left. Pen halts at plot bounds.

Pen moves to specified point and prints label.

Terminates example. (Refer to Saving Steps, page 77.)

The HP-41's flag 17 controls pen movement when the label is completed. If flag 17 is clear, the pen prints the desired label, then moves to a position one character space below the starting point of that label. If flag 17 is set, the pen prints the desired label, then stops at the first character space following the label just printed. Setting flag 17 enables you to print on a single line a label containing more than 24 characters (the size of the ALPHA register). Flag 17 is automatically cleared each time you turn on your HP-41.

Example: Use flag 17 and **LABEL** to print the long label indicated in the following keystrokes.

Character Set

The HP-41 uses several characters that are not contained in the standard character set of most plotters. If any of these HP-41 characters are in the ALPHA register when **LABEL** is executed, they are printed by the plotter according to its own character set.

For example, the HP 7470A Plotter responds to the following HP-41 characters according to this table.

HP-41 Alpha Character	ASCII Character Code	Plotter Response
Δ	13	Returns pen to beginning of same line.
≠	29	Ignored.
↑	94	Prints ^.
Σ	126	Prints ~.

Changing the Label's Location

You can use the following functions to change how the printed characters are oriented relative to the point at which the label is printed. By controlling the label's position and direction, you can locate labels in a variety of ways.

LORG

X **label position**

The **LORG** (*label origin*) function sets the label origin position, which determines where labels are placed relative to the current pen position. The label position can have any value from 1 to 9—the value specifies whether the label is aligned at the left, right, top, or bottom, or is centered. The positions are defined in the following diagram, in which the cross represents the position specified by the HP-41 prior to executing **LABEL**. For example, a value of 8 centers the label vertically and aligns the right end at the pen position.

A value of 0 in the X-register sets the label position to 1. For noninteger values, **LORG** sets the label origin position to the unit digit of the number in the X-register (other digits, including fractions, are ignored). For integer values greater than 9, the **LORG** value is x modulo 10.

Whenever **PINIT** or **LIMIT** is executed, the label origin position is set to 1.

LDIRX **angle**

The **LDIR** (*label direction*) function sets the angle of rotation for printing labels. The angle is specified as positive in the counterclockwise direction and is interpreted according to the HP-41's current angular mode (**DEG**, **RAD**, or **GRAD**).

Whenever you execute **PINIT** or **LIMIT**, the label direction is set to 0 degrees.

Example: Print a label at each 30° interval around a central point. (Bar code for the following program is on page 198.)

Places label in ALPHA.

Appends label direction to label.*

Prints label.
 Increments loop counter.
 Returns to LBL 00.

Terminates program. (Refer to Terminating Examples, page 77.)

Executes program.

The *height* of a character space specifies the vertical distance between the baselines of successive lines. The actual height of the printed character is one-half of the height parameter—the remaining height provides blank space between lines.

The *width* of a character space specifies the horizontal distance between the left edge of each character. The actual width of the printed character is two-thirds of the width parameter—the remaining width provides blank space between characters. (That is, the overall character space is always $1\frac{1}{2}$ times as wide as the actual character width.)

The *aspect ratio* specifies the width-to-height ratio of the printed character—a small value specifies a narrow character, a large value specifies a wide character. Changing the aspect ratio changes the width of the character and the character space:

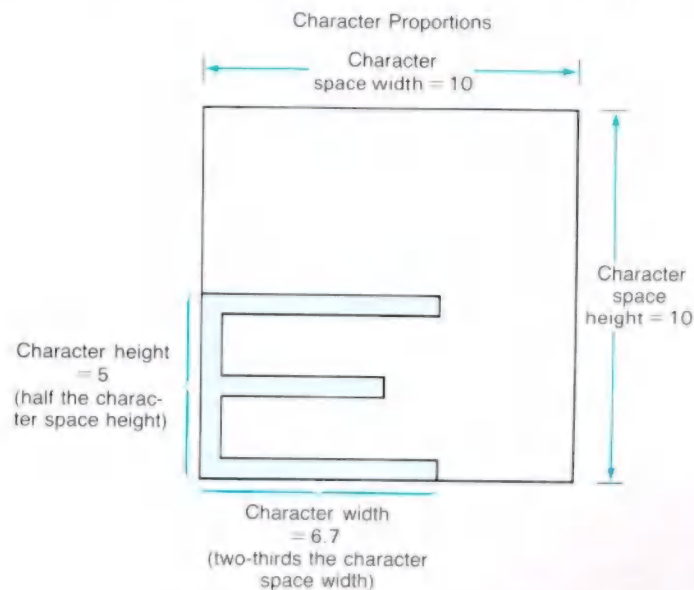

$$\text{character width} = \text{aspect ratio} \times \text{character height}$$

$$\text{character space width} = \frac{3}{2} \times \text{aspect ratio} \times \text{character space height}$$

The *slant* specifies the angle from vertical at which the character “leans” forward—a positive slant specifies a forward “lean,” a negative slant specifies a backward “lean.” Slant affects vertical strokes in a character, but not horizontal strokes.

Whenever you execute `PINIT` or `LIMIT`, the character parameters are set to these values: *height* = 3 GUs, *aspect ratio* = 0.7, and *slant* = 0. These *height* and *aspect ratio* parameters define a *width* of 1.575 GUs.

The following diagram illustrates a character with *height* = 10, *width* = 10, and *slant* = 0. The corresponding *aspect ratio* is 1.3333, which would be used to specify this shape.

`CSIZE`

X `height (GUs)`

The `CSIZE` (*character size*) function sets the height of the character space for subsequent labels—printed characters are half that height. The height is interpreted as GUs, regardless of the current plotting mode.

`CSIZEO`

Z `slant`

Y `aspect ratio`

X `height (GUs)`

The **CSIZEO** (*character size—option*) function sets the height, aspect ratio, and slant parameters. These parameters also determine the character space width. The height is interpreted as GUs, regardless of the current plotting mode. The slant angle is interpreted according to the HP-41's current angular mode (**DEG**, **RAD**, or **GRAD**). (The aspect ratio has no units.)

CSIZEO uses the absolute value of the height and aspect ratio parameters. The slant angle range allowed by the plotter module is between -90° and 90° . Within this range the actual maximum slant angle depends upon your plotter. (Angles outside the $\pm 90^\circ$ range are repeatedly changed by 180° until they fall into this range.)

Example: Write a program that prints seven different character sizes and slants using an aspect ratio of 1. (A bar code listing for the following program begins on page 198 in appendix D.)

Terminates program. (Refer to Terminating Examples, page 77.)

Executes **LABL**.

Executing **LABL** generates the following plot:

Using Axes

You can use the following functions to draw axes, determine their lengths, control the tic marks, and label the axes.

Drawing an Axis

XAXISX **y-intercept (UUs or GUs)**

The **XAXIS** (*x-axis*) function draws a horizontal axis at the specified *y*-intercept. The *y*-intercept is interpreted according to the active plotting mode—either in UUs or in GUs. The axis extends completely across the plotting area—across the plot bounds in UU mode or across the graphic limits in GU mode.

YAXISX **x-intercept (UUs or GUs)**

The **YAXIS** (*y-axis*) function draws a vertical axis at the specified *x*-intercept. The *x*-intercept and the extent of the axis is determined by the active plotting mode—either UU mode or GU mode.

The next four functions draw axes that don't necessarily extend across the entire plotting area and can also include tic marks and labels.

XAXISO

T	<i>x-maximum</i> (UUs or GUs)
Z	<i>x-minimum</i> (UUs or GUs)
Y	<i>tic-spacing</i> (UUs or GUs)
X	<i>y-intercept</i> (UUs or GUs)

The **XAXISO** (*x-axis option*) draws an x-axis between the specified minimum and maximum x-values and at the specified y-intercept, including tic marks at the specified spacing (described below).

YAXISO

T	<i>y-maximum</i> (UUs or GUs)
Z	<i>y-minimum</i> (UUs or GUs)
Y	\pm <i>tic-spacing</i> (UUs or GUs)
X	<i>y-intercept</i> (UUs or GUs)

The **YAXISO** (*y-axis option*) function draws a y-axis between the specified y-values and the specified x-intercept, including tic marks at the specified spacing (described next).

Specifying Tic Marks

Tic Spacing. The tic-spacing parameter specifies the spacing between plotted tic marks. If the tic-spacing number in the y-register is positive, tic marks begin at the smallest value on the axis and are spaced equally along the axis in the positive direction. If the tic-spacing number is negative, tic marks begin at the highest value on the axis and are spaced equally in the negative direction. For example, consider these axes plotted from 0 to 10:

If the axis extends outside the plotting area, tic marks are located according to the intended starting point, rather than where the axis actually enters the plotting area.

When you want to plot an axis with a specified maximum and minimum, but you don't want any tics to appear on the axis, use a tic spacing value that exceeds the length of the axis.

Tic Length. The length of each plotted tic mark is related to the length of the plotting area. For example, tic marks on a y-axis are horizontal, and their length is proportional to the horizontal dimension of the plotting area. Similarly, the vertical tic marks on an x-axis are proportional to the vertical dimension of the plotting area. You can change the tic length using the following function.

TICLEN

X	<i>tic length</i> (%)
---	-----------------------

The **TICLEN** (*tic length*) function sets the tic length to the specified percentage of the graphic limits. It sets the vertical and horizontal tic lengths equal to a percentage of the vertical and horizontal dimensions of the graphic limits—the dimensions of the plot bounds don't affect the tic length, nor does the plotting mode. This percentage applies to both the x- and y-axes. (If the graphic limits have unequal dimensions, vertical and horizontal tic marks have unequal lengths.)

Tic marks are drawn with the specified length on each side of the axis. For example, a specified tic length of 2 percent produces tic marks with an actual length of 4 percent (2 percent on each side of the axis). However, if the axis is drawn at the edge of the plotting area, the tic marks are drawn only inside the area (2 percent long, in the same example).

TICLEN uses the absolute value of the tic length parameter. Whenever you execute **PINIT** or **LIMIT**, the tic length is set to your plotter's default tic length value.

Example: Set up a plotting area and draw x-axes at $y = 0$ and $y = 50$, each having large-size tic marks. Then draw minor tic marks on a portion of the upper x-axis.

} Draws the x-axis portion of the grid.

} Draws the y-axis portion of the grid.

} Terminates the example. (Refer to Terminating Examples, page 77.)

You can draw various types of partial grids by:

- Specifying an `XAXISO` or `YAXISO` range that is smaller than the extent of the axis.
- Using `TICLEN` to set a tic length that is shorter than the length of the axis.

Drawing a Labeled Axis

Two functions, `LXAXIS` and `LYAXIS`, provide automatic labeling for your axis plotting operations.

These functions operate in the same way as `XAXISO` and `YAXISO`, except that the plotter also prints a numeric label at each tic mark it draws on the axis. The labels are printed in the area between the plot bounds and the graphic limits. Be sure to allow enough room around the plot bounds so that the labels are not clipped at the graphic limits.

Axis labels are formatted according to the HP-41 display format. The labels use the current character size (height, aspect ratio, and slant) and set the label direction (which may have been set by `LDIR`) to 0. The current `LOG` position isn't changed or used. After the axis is drawn, the ALPHA register contains the last label printed.

`LXAXIS`

T	<i>x-maximum</i> (UUs or GUs)
Z	<i>x-minimum</i> (UUs or GUs)
Y	<i>tic spacing</i> (UUs or GUs)
X	<i>y-intercept</i> (UUs or GUs)

The **LXAXIS** (*label x-axis*) function draws the specified x-axis and labels its tic marks *below the plot bounds*. If the tic spacing parameter is positive, the labels are printed vertically (perpendicular to the x-axis); if the tic spacing parameter is negative, the labels are printed horizontally (parallel to the x-axis). Be sure to check the format, size, and spacing of horizontal labels to avoid overlap.

LXAXIS

T	y-maximum (UUs or GUs)
Z	y-minimum (UUs or GUs)
Y	tic spacing (UUs or GUs)
X	x-intercept (UUs or GUs)

The **LYAXIS** (*label y-axis*) function draws the specified y-axis and labels its tic marks *to the left of the plot bounds*. The labels are always printed horizontally (perpendicular to the y-axis).

Example: Using the graphic limits and plot bounds defined by the SET program (page 76), draw an x-axis at $y = 0$ and label this axis at intervals of 10 UUs. Also draw a y-axis at $x = 50$ and label it at intervals of 20 UUs.

Digitizing

Contents

Introduction	104
Selecting a Point (DGTIZE)	104
Identifying a Point (WHERE)	106
Digitizing Plot Bounds (LOCATD)	106

Introduction

The functions described in this section enable you to use your plotter's manual pen control keys to obtain x, y coordinate data from points on the plotting area. This process is called *digitizing* and is essentially the inverse of plotting. That is, plotting sends x, y coordinate values to the plotter, which then moves the pen to the specified location on the plotting area; digitizing involves moving the plotter's pen to a point on the plotting area and returning the x, y coordinates of that point to your HP-41. This feature allows you to "trace" an illustration by determining the coordinates of several of its points, and to use those coordinates as inputs to replot the illustration. By changing the scale, you can reproduce the same illustration in various sizes. The first example in this section uses the **PLREGX** function in a program that plots an illustration from data accumulated by digitizing.

When you execute the examples in this section, use the pen arm control keys on your plotter. To enter a point during a digitizing operation, press the *plotter's* ENTER key. The x, y coordinate values and the pen status will be returned to the HP-41.

On plotters equipped with a digitizing sight, the sight can be placed in the pen holder as if it were a pen. The digitizing procedure is the same as that for a plotter without a digitizing sight.

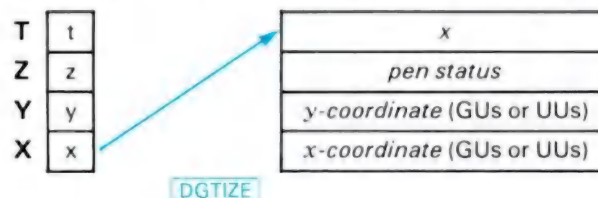

Selecting a Point

DGTIZE

The **DGTIZE** (*digitize*) function prompts you with the message **ENTER POINT**. Then:

1. If the pen is not already at the point you want to enter into the HP-41, move the pen to the desired point.
2. If necessary, use **PENUP**, **PENDN**, or the pen elevation keys on your plotter to place the pen in the desired up or down position.
3. Press your plotter's ENTER key.

DGTIZE enters the x - and y -coordinates of the pen's position—in the current scale units—into the HP-41's X- and Y-registers, and enters the current pen status (0 = "up", 1 = "down") in the Z-register.

If **DGTIZE** is executed in a running program, program execution resumes after you press the plotter's ENTER key. If you do not press this key within approximately 10 minutes of executing **DGTIZE**, the HP-41 turns itself off.

The *pen status* parameter is useful when you are digitizing under program control. That is, if you are storing digitized coordinates in HP-41 data registers that will later be accessed by **PLREGX**, you can design the program to place an Alpha character in a register whenever a pen "up" status must be communicated to the **PLREGX** function. (Refer to the **PLREGX** function description on page 83.)

Example: Use the following program to digitize a simple design that connects 10 points. (Ensure that data registers R₀₀ through R₂₂ in your HP-41 are available.)

PRGM

Using the preceding program, digitize the outline of the star shown below to the left (or a facsimile). Then, by changing the **LIMIT** parameters, plot on another sheet the series of stars shown below to the right.

The procedure for this example is:

1. Execute the SET program to initialize the plotter and HP-41. (Refer to Initializing the HP-41 for Examples, page 76.)
2. Move pen to (50,50) and place a facsimile of the star on the platen so that it is centered under the pen.
3. Execute DIG and digitize the indicated points on the star. (You should begin and end at the same point.)
4. Execute **SETGU**, move the pen to point (0, 0), and place a new sheet of paper in the plotter. (You may then have to retrieve the pen from its stall.)
5. Place the number 1.022 in the X-register (to indicate data registers R₀₁ through R₂₂) and execute **PLREGX** to plot the points that you digitized in step 3.
6. Reduce the graphic limits by 50 mm on all sides of point (50, 50) by entering 56, 206, 57, and 137, and executing **LIMIT**. Then perform step 5 again.
7. Further reduce the graphic limits by 25 mm on all sides of point (50, 50) by entering 81, 181, 82, and 112, and executing **LIMIT**. Then perform step 5 again.
8. Press 0 **ENTER**↑, then execute **PEN** to store the pen and **MOVE** to display the stars.

The preceding information is only a sample of how data accumulated by **DGTIZE** might be used. The procedures you use for your own applications are likely to vary according to the nature of each problem.

Identifying a Point

The **DGTIZE** function recalls the point to which *you* moved the pen using the plotter's keys. The **WHERE** function recalls the point to which *the HP-41* last moved the pen.

WHERE

The **WHERE** (*where is pen*) function enters into the HP-41's X- and Y-registers the *x*- and *y*-coordinates of the point specified by the last pen movement function performed by the HP-41.* (Pen positions resulting from movement using the plotter's pen control keys are ignored.) The pen status is placed in the Z-register; it can either be used as described for the preceding **DGTIZE** function or ignored. The stack lifts in the same way that it does when you execute **DGTIZE**. **WHERE** does not terminate program execution.

WHERE allows you to easily determine the pen position, store it for future reference, and then perform some other plotting task. When you are ready, you can recall the stored data and return to the original point. This may be particularly useful for determining the pen position at the end of a **LABEL** operation.

Digitizing Plot Bounds

You can define the plot bounds by moving the pen to the desired corner points. For example, this enables you to locate your plot properly on a printed sheet.

LOCATD

The **LOCATD** (*locate by digitizing*) function allows you to specify the plot bounds by digitizing the two opposite corners. The plotter sends the coordinates of the specified corner points to the HP-41. The HP-41 interprets the coordinates as GUs, so be sure that the HP-41 is set to GU mode (or, if in UU mode, that the user scale is the same as the graphic scale) before using **LOCATD**.

*If the last intended point was far outside the physical limits of the plotter, **WHERE** may return an *x*- or *y*-coordinate that is limited according to the numerical range of the plotter.

When you execute **LOCATD**, **ENTER POINT** appears in the display. You then use your plotter's keyboard to:

1. Position the pen at the lower left-hand point of the desired plot bounds and press the *plotter's* ENTER key.
2. When **ENTER POINT** again appears in the display, move the pen to the upper right-hand point of the desired plot bounds and again press the plotter's ENTER key.

After you complete the preceding two steps the plotter module sets the specified plot bounds and places in the stack the maximum and minimum for each axis, as shown in the following illustration.

T	<i>x-minimum</i> (GUs)
Z	<i>x-maximum</i> (GUs)
Y	<i>y-minimum</i> (GUs)
X	<i>y-maximum</i> (GUs)

Plot bounds you set using **LOCATD** are the same as the ones you set using the **LOCATE** function described on page 73. If you execute **LOCATD** with the corner points of the plot bounds outside the graphic limits, the resulting plot bounds are truncated where they intersect the graphic limits. (The *x*- and *y*-maximums and minimums placed in the stack will be those of the corner points you attempted to enter as plot-bound parameters.)

If you do not enter a point within approximately 10 minutes of the time an **ENTER POINT** prompt appears, the HP-41 turns itself off.

Introduction

The plotter module enables you to plot standard HP-41 bar code* for the HP 82153A Optical Wand and three types of bar code for scanning devices used in other bar code systems. The module also enables you to print HP-41 bar code on the HP 82162A Thermal Printer. If you will be using only the printer to generate bar code, read the information under Terminology, page 109, then turn to Printing HP-41 Bar Code on the HP 82162A Thermal Printer, page 133. If you will be using a plotter to generate bar code, you should read sequentially through the topics in this section. If you have not already read the *HP 82153A Wand Owner's Manual*, you should do so before proceeding in this section.

*That is, all bar code you can read using the HP 82153A Optical Wand. This bar code includes the following types: program, numeric data, sequenced data, Alpha-Replace, Alpha-Append, paper keyboard, and direct execution. You can also generate special bar code (for use with the wand's WNDSCN function).

The easiest and most direct way to generate HP-41 data and program bar code is to use the PLOTBC and XBC programs. PLOTBC interacts with you to determine what HP-41 bar code you want, then uses XBC to plot the bar code in sequential, left-justified rows. This method enables you to generate HP-41 program bar code and most types of HP-41 data bar code in a default format. When you want to generate any of these same bar code types at selective pen positions, you can use the preprogrammed subroutines described under Bar Code Subroutines on page 120. To generate unlabeled bar code, paper keyboard or direct execution bar code, or bar code that is designed for scanning by devices other than the HP 82153A Optical Wand, refer to the functions and procedures described under Basic Bar Code Functions (page 127) and Utility Bar Code Functions (page 136).

Terminology

It is not necessary to understand the details of bar code terminology before you begin printing program or data bar code. However, to help you more easily use the material in this section, you may want to read through the following brief definitions of the more commonly used bar code terms as they apply to the HP 82184A Plotter Module:

Absolute Plotting Units: The pen movement parameters used by your plotter are internally calculated in absolute plotter units (APUs). There are 40 APUs per millimeter. The bar code width and height parameters used by the plotter module are expressed in APUs.

Alternate Bar Code: Any type of non HP-41 bar code in which the spaces and/or the bars represent data. In the plotter module, type numbers 1 through 3 designate alternate bar codes.

Bit: A binary digit of data. (That is, a 0 or a 1 digit.)

Bit Pattern: A grouping of bits in the ALPHA register that represent a particular data item.

Byte: An eight-bit unit of data held in a computer register. Also, a unit of memory space. (Refer to your HP-41 owner's manual.)

Checksum: A parameter used for error checking—usually the sum of all data bytes in a row of bar code.

HP-41 Bar Code: The bar code designed by Hewlett-Packard to be read by the HP 82153A Optical Wand.

Running Checksum: A parameter used for error checking in program bar code. The checksum for each row represents the sum of the current row and all previous rows in the program.

Controlling Bar and Space Proportions

The width of a pen you use to plot bar code affects the proportions between the widths of the bars and the widths of the spaces. Because wear increases pen width, you must periodically determine pen width and recalibrate the plotter module according to the current pen width. Otherwise, the bar/space width proportions can become distorted and therefore make the bar code difficult for the wand to read.

The plotter module specifies a bar or space width by the number of APUs a pen of a given width must move to travel across that bar or space. The plotter module's computation of how many APUs to allow for a bar or space depends upon the *bar code size parameter* maintained in the I/O buffer. This parameter, which specifies pen width and several bar and space widths, is automatically set to a default value when you first create the I/O buffer by executing `PINIT`. This default value is compatible with the 0.3-mm (12-APU) pen. As long as you generate HP-41 bar code with a pen having this width, the bars and spaces in your bar code will be correctly proportioned. However, if either the actual width of your pen differs from

the width contained in the size parameter or you want to generate non HP-41 bar code, the bar/space proportions in your bar code may be distorted. This can render the bar code difficult or impossible to read with your scanning device. To eliminate this distortion, use the PWIDTH program (provided in this manual) and the plotter module's **BCSIZE** function.

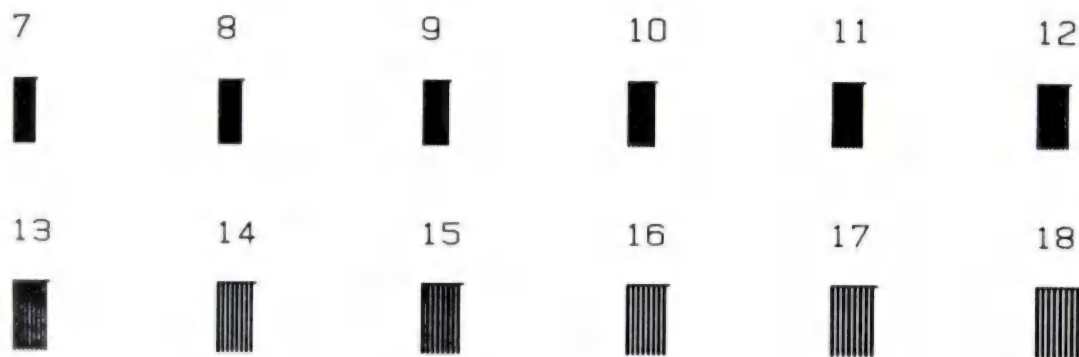

Measuring the Pen Width

PWIDTH

The PWIDTH (*pen width*) program uses the pen in stall 1 to plot a series of null bytes of bar code. The bytes are plotted in two rows, the first of which begins near the lower-left corner of the plotting area. Each byte is plotted using a different pen width value in the bar code size parameter. PWIDTH begins with a pen width of 7 APUs and terminates with a pen width of 18 APUs. Each byte is labeled to indicate the pen width value used for that byte. The first few bytes usually appear as solid blocks. The last few bytes show increasingly wider spaces between the bars. The first byte having a visible space between any of the bars indicates the approximate pen width. PWIDTH uses data registers R₀₀ through R₀₂.

The PWIDTH program helps you to approximate the width of the pen you want to use for plotting bar code. Using the pen width value indicated by PWIDTH, you then execute the **BCSIZE** function (which is described on the next page) to calibrate the plotter module to the width of your pen. (If you are generating HP-41 bar code, you can usually perform this calibration by placing zero in the Y-register and pen width—from executing PWIDTH—in the X-register, then executing **BCSIZE**.)

The following illustration shows the result of executing PWIDTH. In this case, PWIDTH indicates a pen width of approximately 13 APUs.

*PWIDTH Must Always Be Followed By **BCSIZE**.* Executing PWIDTH changes the bar code size parameter maintained by the I/O buffer. Thus, when you execute PWIDTH, you must then reset the bar code size parameter using the **BCSIZE** function. If you are generating HP-41 bar code, you can usually reset the size parameter by simply placing zero in the Y-register, placing the pen width indicated by PWIDTH in the X-register, and executing **BCSIZE**.

Example of PWIDTH Execution: Use the bar code on page 203 or the annotated program listing on page 169 to enter the PWIDTH program into your HP-41. Place in stall 1 a pen you can use for plotting bar code. Then:

1. Turn your plotter off and on (to set it to its default graphic limits).
2. Place a new sheet of paper in the plotter.

3. Execute PWIDTH, examine the resulting plot, and identify the pen width. (PWIDTH executes `PINIT`, which, in this case, creates a new I/O buffer.)
4. Calibrate the plotter module with the new pen width by placing zero in the Y-register, placing the pen width from step 3 in the X-register, then executing `BCSIZE`.

Keystrokes

`XEQ ALPHA PWIDTH`
`ALPHA`

Display

`XEQ PWIDTH _`

 0.0000

Plots and labels 12 null bytes. After last byte is plotted, pen returns to stall.

Examine the bytes generated by PWIDTH. The lowest-numbered byte showing a gap between any two bars indicates the approximate width in APUs of the pen you are using.

Note: PWIDTH results are subject to visual interpretation. For this reason you may find that, with some pens, you cannot clearly distinguish which of two or three adjacent width values you should use with `BCSIZE`. In such cases you should experiment with each of the values to identify the optimum width value to use. To do so, generate a separate row of bar code at each possible width value, then compare the rows visually and by reading with your bar code scanning device.

To calibrate your plotter module to a pen width indicated by PWIDTH, place 0 in the Y-register and the pen width (*pp*) in the X-register, then execute `BCSIZE`. After you use this method to calibrate the plotter module to the pen you are using, you are ready to begin plotting bar code.

Keystrokes

`0` `ENTER` ↑
pp (Key in pen width.)
`BCSIZE`

Display

0.0000
pp.0000
pp.0000

Enters 0 in the Y-register.

Enters pen width in APUs.

Sets bar code size parameter.

(Leave the page in your plotter for use in the next example.)

Periodic Adjustments. As indicated earlier, pen wear is a factor that can gradually introduce distortion into the bar and space proportions of your bar code. Thus, you should periodically reexecute PWIDTH and `BCSIZE` to ensure that the bar code size parameter remains calibrated to the current pen width.

Changing the Bar Code Size and Type

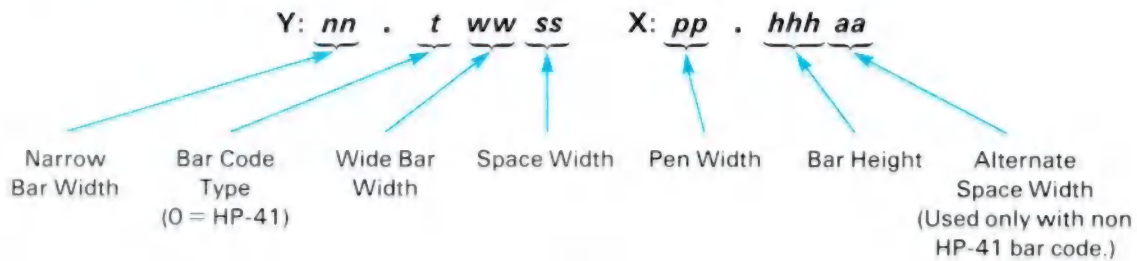

In the preceding discussion of PWIDTH you saw that you can reset the bar code size parameter for HP-41 bar code by simply keying in the pen width and executing `BCSIZE`. However, if you want to adjust the individual bar and space widths for HP-41 bar code, or if you want to specify an alternate bar code type, you will need to specify several elements of the bar code size parameter when you execute `BCSIZE`. If you are new to plotting bar code, you may not need to understand such details of `BCSIZE` operation until you have gained more experience. In this case, go on to Using a Program to Generate Bar Code on page 114 and resume reading. Otherwise, continue with the following description of `BCSIZE`.

`BCSIZE`

Y	<i>nn.twwss</i>
X	<i>pp.hhhaa</i>

The `BCSIZE` (*bar code size*) function uses the absolute value of the parameter elements in the X- and Y-registers to adjust the bar and space proportions. This compensates for variance in pen width and/or the requirements of an alternate bar code type that you may want to generate. With the exception of the bar code type number (*t*), the parameters are interpreted in absolute plotter units (APUs).

The Bar Code Size Parameter. The bar code size parameter, which consists of the elements illustrated below, controls bar width, space width, and bar code type.

The elements in this parameter are set to a series of default values when you execute **PINIT** to create the I/O buffer. However, if the I/O buffer already exists, the elements in the bar code size parameter are not affected by executing **PINIT**. The default element values are designed to produce correctly proportioned HP-41 bar code when you use a pen having a 0.3-mm (12-APU) width to plot the bar code. The **PINIT** column in the following chart shows the default value for each element.

When you execute **BCSIZE**, the parameter elements are set according to the values in the X- and Y-registers. However, where zeros are used to represent elements in the bar code size parameter, **BCSIZE** automatically sets those elements to values that are compatible with HP-41 bar and space width proportions. The **BCSIZE** column in the following chart shows how **BCSIZE** calculates such values.

Thus, as indicated in the PWIDTH discussion on page 111, you can set the bar code size parameter for HP-41 bar code by executing **BCSIZE** with zero in the Y-register and the correct pen width element in the X-register. Also, you can execute **BCSIZE** with zero in both the X- and Y-registers to set all elements in the bar code size parameter to their **PINIT** default values.

Elements of the HP-41 Bar Code Size Parameter

Register	Element	Application	Default When PINIT Creates I/O Buffer	BCSIZE Calculation For Any Unspecified Element	Element Range
Y-Register	<i>nn</i>	Narrow Bar Width	18 APUs	$nn = pp + pp/2$	0-99 APUs (0-2.5 mm)
	<i>t</i>	Bar Code Type (Used by BCO)	Type 0	0	0 thru 3
	<i>ww</i>	Wide Bar Width	30 APUs	$ww = 2nn - pp/2$	0-99 APUs (0-2.5 mm)
	<i>ss</i>	Space Width (For Types 0, 1 and 3) Narrow Space Width (For Type 2)	21 APUs	$ss = nn + 3$	0-99 APUs (0-2.5 mm)
X-Register	<i>pp</i>	Pen Width	12 APUs	12	0-99 APUs (0-2.5 mm)
	<i>hhh</i>	Bar Height	350 APUs	350	0-999 APUs (0-25 mm)
	<i>aa</i>	Alternate Space Width (For Types 1 and 2)	0	0	0-99 APUs (0-2.5 mm)

Example of How to Use `BCSIZE`: Compare the results of using three different bar code size parameters. Do this by generating the same bar code row three times; once for each parameter setting. The rows you generate will be similar to the following three rows. However, the width of the pen you use will control the actual width of your bars and spaces.

**Keystrokes****Display**`PINIT`

Initializes the I/O buffer. If the buffer already exists, this function does not affect the current bar code size parameter.

`1 PEN 35 MOVE`

35.0000

Selects and positions pen for first row.

For your first setting, use the default bar code size parameter. This parameter assumes the HP-41 bar code type (type 0), a bar height of 350 APUs, a pen width of 12 APUs, and a series of default bar and space values based on the pen width. (Refer to the `PINIT` column in the chart on page 112.)

Keystrokes**Display**`0 ENTER↑`

0.0000

Places zero in the X- and Y-registers.

`BCSIZE`

0.0000

Sets the elements in the bar code size parameter.

`123 BCX BC`

3.0000

Uses bar code functions to generate a row of bar code. (The "3" results from the `BCX` function, which is described later in this section.)

For your second setting, use a pen width element of 10 APUs and a bar height element of 300 APUs. Use zeros in the remaining element positions. (This causes `BCSIZE` to set these elements in proportion to the specified pen width—refer to the `BCSIZE` column in the chart on page 112.)

Keystrokes**Display**`40 ENTER↑ 35 MOVE`

35.0000

Positions pen for second row.

`0 ENTER↑`

0.0000

Specifies 0 for the *nn*, *t*, *ww*, and *ss* parameter elements.

10.3

10.3 _

Specifies 10 for the *pp* element and 300 for the *hhh* element.

`BCSIZE`

10.3000

Sets the elements in the bar code size parameter.

`123 BCX BC`

3.0000

Uses bar code functions to generate a row of bar code.

For your third setting, use a pen width element of 16 APUs and a bar height element of 225 APUs. For the *nn* and *ss* elements, add 5 APUs to the value that `BCSIZE` would calculate for each of these if they were unspecified. Similarly, add 10 APUs to the *ww* element value. (That is, add 5 to the results of the *nn* and *ss* equations in the chart on page 112, and add 10 to the result of the *ww* equation.)

If $pp = 16$

then $nn = pp + pp/2$
 $= 24$

$ww = 2 \times nn - pp/2$
 $= 40$

$ss = nn + 3$
 $= 27$

and $nn + 5 = 29$
 $ww + 10 = 50$
 $ss + 5 = 32$

Because this example is intended for HP-41 type bar code, use zero for both the **t** and the **aa** elements.

Keystrokes	Display	
70 ENTER 35 MOVE	35.0000	Positions pen for next row.
29.0	29.0 _	Keys in nn and t .
50	29.050 _	Keys in ww .
32	29.05032 _	Keys in ss .
ENTER	29.0503	Enters nn.twwss in the Y-register.
16.	16. _	Keys in pp .
225	16.225 _	Keys in hhh .
BCSIZE	16.2250	Sets the elements in the bar code size parameter.
123 BCX BC	3.0000	Uses bar code functions to generate a row of bar code.

This concludes the **BCSIZE** example. Because this example altered the bar code size parameter in your plotter module, use **PWIDTH** and **BCSIZE** to recalibrate the size parameter before you move on to the next topic.

Keystrokes	Display	
XEQ ALPHA PWIDTH	XEQ PWIDTH _	Executes PWIDTH . You should now determine approximate pen width (pp) from resulting plot for use in next step.
ALPHA	3.0000	
pp BCSIZE	pp.0000	Keys in pen width indicated by preceding step and calibrates plotter module for that width.

Further **BCSIZE Operating Details.** When you execute **BCSIZE**, if the integer portion of the number in either the X- or Y-register (the pen width or narrow bar parameter element) contains more than two digits, only the rightmost two digits of such an integer will be used. Any combination of **pp** and/or **nn** parameters that results in an overflow in **nn** or **ww** causes the computer to display the **DATA ERROR** message.

Note: When the bar code size parameter has been calibrated to a large pen width, the plotting area may not be wide enough for a bar code row. For example, when the bar code size parameter is set to a pen width of 18 APUs, rows can be no longer than 12 bytes (where the default plotting area is used).

The **BCSIZE** function is designed to calibrate the plotter module for pen widths in the range of 7 through 18 APUs. Specifying pen widths outside of this range can reduce the accuracy of the bar and space proportions in your bar code.

Using a Program to Generate Bar Code

Many of your bar code generation projects may require only that you produce several rows of data or program bar code on a sheet of paper. This manual provides you with a pair of programs, **PLOTBC** and **XBC**, that you can use together to complete such tasks. **PLOTBC** is an interactive program that prompts you to select a bar code type and to key in the information needed to plot the desired bar code. **PLOTBC** then executes the subroutine in **XBC** that plots and labels the bar code. **PLOTBC** automatically positions the pen for each row and prompts you to insert a fresh page when needed.

PLOTBC cannot be used without XBC. (The **XBC** program contains the subroutines that plot and label individual rows or bar code and can be used independently of **PLOTBC**. Independent use of **XBC** is

described under Bar Code Subroutines on page 120.) PLOTBC generates the following five types of bar code.:

- X-Register Data **D**
- X-Register Sequential Data **SD**
- ALPHA Register Data **A**
- Alpha-Append Data **AA**
- Program **P**

Using an HP 82153A Optical Wand, you can enter PLOTBC and XBC into your HP-41 by:

1. Scanning the PLOTBC program bar code on pages 199 through 201.
2. Executing   .
3. Scanning the XBC program bar code on page 207 through 209.

If you do not have a wand, you can load the programs from the keyboard by using the PLOTBC program listing on page 161 and the XBC program listing on page 171. PLOTBC uses 56 memory registers and data storage registers R₀₀ through R₀₃. XBC uses 52 memory registers and data storage registers R₀₀ and R₀₁.

Using PLOTBC

Key Assignments. PLOTBC operation is controlled by the *main prompt* and the top row keys, as shown below:

The Main Prompt and Corresponding Top Row Keys

D	SD	A	AA	P
				

When the main prompt is displayed, you select the desired bar code type by pressing the corresponding top row key.* The program then prompts you for the appropriate data or program information, generates the bar code, and prompts you for either the next data entry or the next bar code type.

Note: If you assign a function or program to any top row key, pressing that key while the main prompt is displayed (and the User keyboard is active) executes the assigned function or program instead of continuing with PLOTBC bar code operations.

Pens. PLOTBC uses pen number 1 to plot bar code and pen number 2, if available, to print labels.

Example of PLOTBC Operation: Enter PLOTBC and XBC into program memory. Then plot bar code for the four data types and for the SET program you used earlier in this manual (refer to Initializing the HP-41 for Examples, page 76). To ensure that the current graphic limits are large enough for the bar code you are about to generate, turn your plotter off, then on, before you begin.

Keystrokes

Display

  PLOTBC

XEQ PLOTBC _

Executes PLOTBC.

INSERT PAGE

Prompts you to insert a sheet of paper into the plotter. Press  when you are ready to proceed.

D SD A AA P

Prompts you to select a bar code type.

DATA?

Selects X-register data bar code type and prompts you to key in your data.

12.34 

DATA?

Enters data and plots labeled bar code, positions pen to begin next row, and prompts you for another data entry.

*Line 04 of the PLOTBC program sets flag 27, which is the HP-41's User keyboard flag. The top row keys are used with PLOTBC to specify the desired bar code type in the same way that they are used with the Utility Plotting Program to specify a plotting routine. Refer to User Keyboard, Key Assignments, and Keyboard Overlay, page 21.

Keystrokes

Display

[ALPHA] [ABC] [R/S]

DATA?

Enters data, plots labeled bar code, positions pen to next row, and prompts for next data entry.

[R/S]

D SD A AA P

When no data entered, returns you to main prompt.

[1/x]

SEQ = 0?

Selects sequential data bar code and prompts you to verify that 0 is the sequence number for this row of data bar code.

[R/S]

DATA?

When no value keyed in, assumes that 0 is the correct sequence number and prompts you for data input.

56.78 [R/S]

SEQ = 1?

Enters data and plots labeled bar code, positions pen to next row, and prompts you to verify that 1 is the sequence number for the next data bar code row.

[R/S]

DATA?

Assumes that 1 is the correct sequence number and prompts you for data input.

9.01 [R/S]

SEQ = 2?

Enters data and plots labeled data bar code. Positions pen to next row and prompts you to verify next sequence number.

[R/S]

DATA?

Assumes that 2 is the correct sequence number and prompts you for data input.

3.23 [R/S]

SEQ = 3?

Enters data and plots labeled bar code. Positions pen to next row and prompts you to verify next sequence number.

[R/S]

DATA?

Assumes that 3 is the correct sequence number and prompts you for data input.

[R/S]

D SD A AA P

When no data entered, returns you to main prompt.

[√]

A DATA?

Selects ALPHA register bar code type and prompts you to key in your data.

XXX [R/S]

A DATA?

Enters alpha data. Plots labeled bar code, positions pen to next row, and prompts for next data entry.

[R/S]

D SD A AA P

When no data entered, returns you to main prompt.

[LOG]

AA DATA?

Selects Alpha-Append bar code type and prompts you to key in your data.

YYY [R/S]

AA DATA?

Enters alpha data. Generates labeled bar code, positions pen to next row, and prompts for next data entry.

[R/S]

D SD A AA P

When no data entered, returns you to main prompt.

[LN]

NAME?

Selects program bar code type and prompts you to key in your data.

SET [R/S]

ROW = 1.16?

Selects the SET program and prompts you to verify that 1 is the row number to start with and 16 is the maximum byte length for each row.

[R/S]

} ————— }

Verifies row and byte number. Plots program bar code (in approximately 6 minutes using the HP 7470A Plotter) and, because no space remains on the page, prompts you to insert a page.

SET

ROW 1: LINES 1-5

ROW 2: LINES 5-12

ROW 3: LINES 13-21

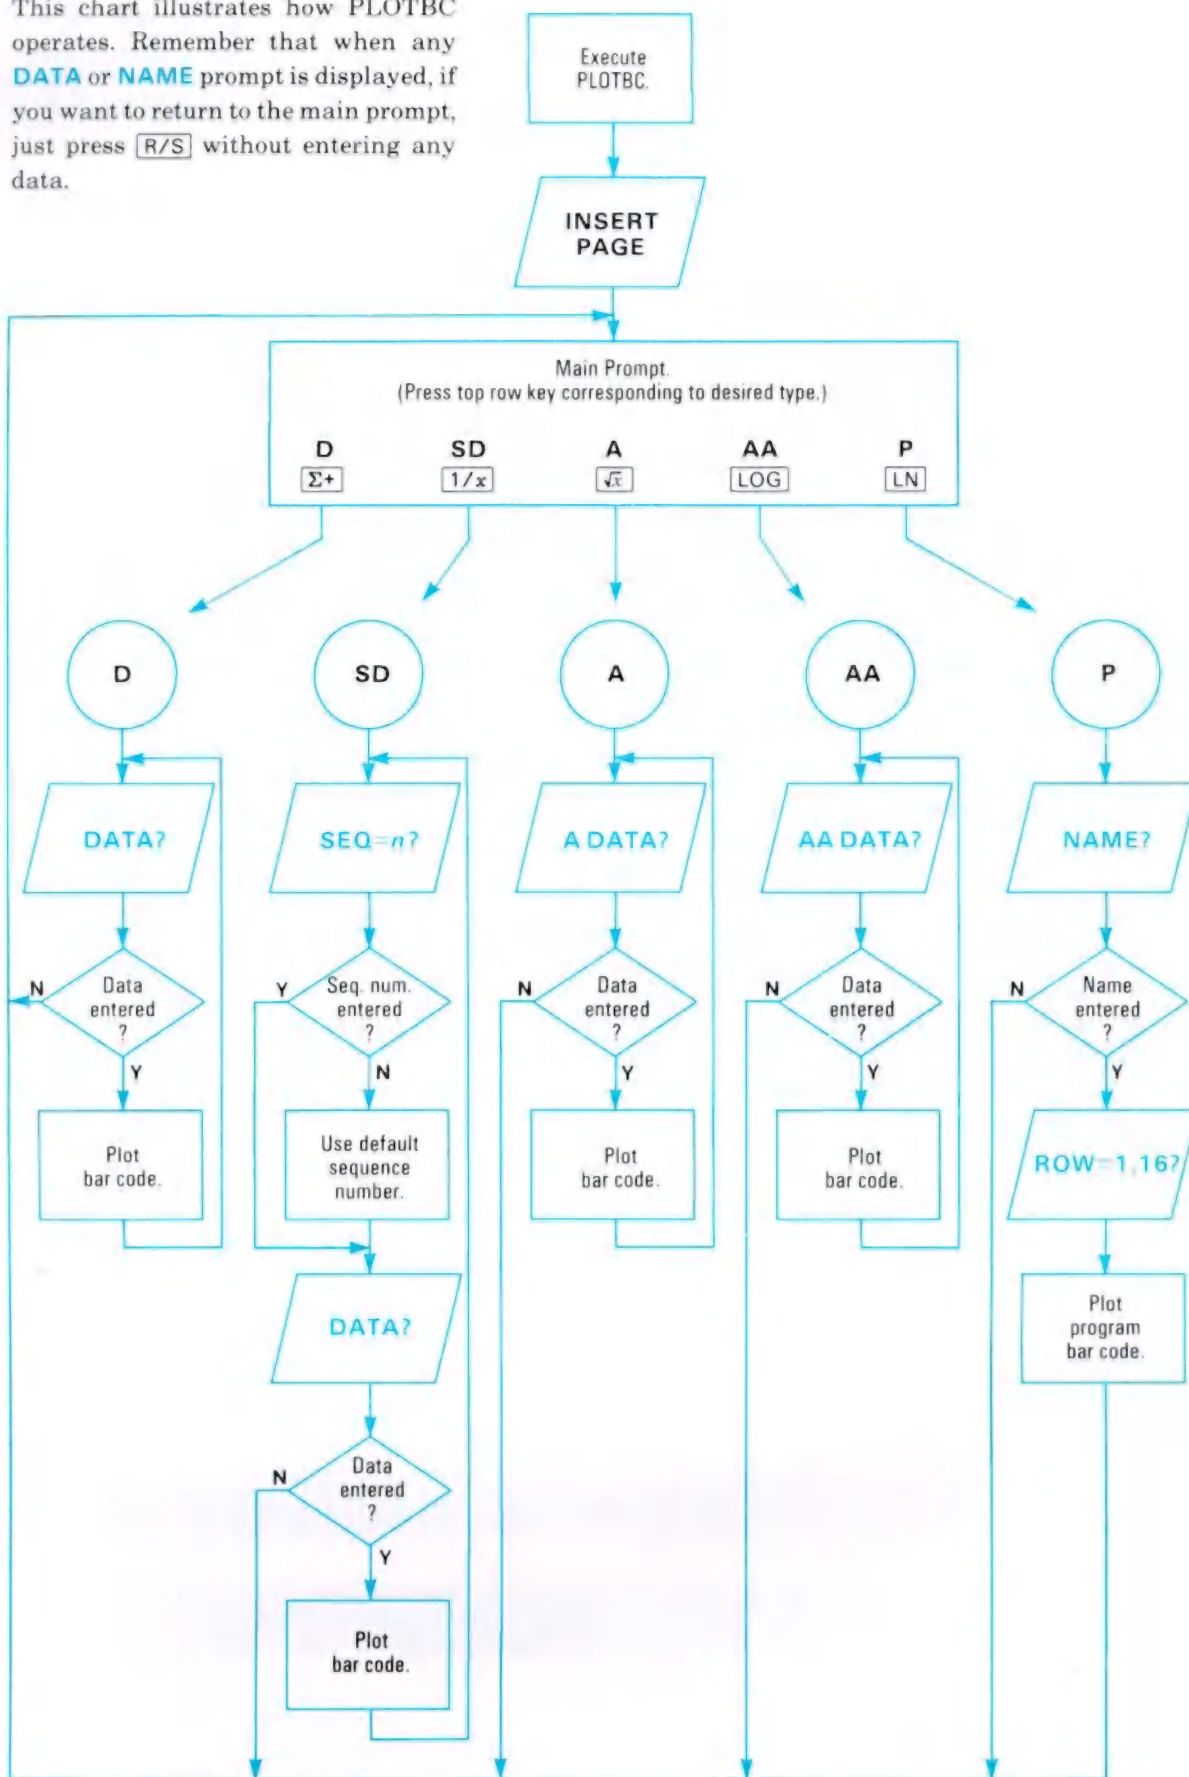

ROW 4: LINES 21-28

ROW 5: LINES 28-28

This chart illustrates how PLOTBC operates. Remember that when any **DATA** or **NAME** prompt is displayed, if you want to return to the main prompt, just press **R/S** without entering any data.

Whenever the HP-41 is set to any line in the PLOTBC program and the User keyboard is active, the following key assignments are also active:

- **[a]**: Executes PLOTBC. (For keys to press, refer to the HP-41's back label.)
- **[b]**: Returns you to the main prompt.
- **[c]**: Moves pen to the next bar code row.
- **[d]**: Moves pen to the preceding bar code row.
- **[e]**: Replot a specific row of bar code. When you press ■ **[e]**, the X- and Y-registers must contain the same data as is shown for the PBC subroutine (page 124), and the pen must be positioned to plot the row. (If you have to move the pen, use either ■ **[c]** or ■ **[d]**, as described below, under Changing Rows.)

The PLOTBC program provides you with an easy method for producing consecutive rows of bar code. If this program meets your bar code generation needs, you may not need to use the plotter module's individual bar code subroutines and functions. The following information describes PLOTBC operating conditions that you may need to remember when you use the program in your applications.

PLOTBC Operating Notes

Ensuring Adequate Graphic Limits. PLOTBC executes **PINIT**, which maintains the current graphic limits, but returns all other plotter, module, and I/O buffer settings (except the bar code size parameter*) to their default values. Thus, the plotting area and user units (UUs) are set to the dimensions of the current graphic limits and graphic units (GUs). Because the character spaces for the labels automatically default to 3 GUs, the current dimensions of the graphic limits determine the physical height of your bar code label characters. The dimensions of the bar code are specified in plotter units and are not affected by the dimensions of the graphic limits. To ensure labels of the size generated in the preceding example, set the plotter module to your plotter's default graphic limits by turning the plotter off, then on, before you begin a bar code plotting session with PLOTBC.

Note: If PLOTBC encounters an edge of the plotting area while plotting bar code, the portion of the bar code row that is outside the boundary is not plotted. In such cases, the plotter will appear to pause because the HP-41 will still perform all calculations for the current row, even though some part of the row is not being plotted.

Pen Positioning. Each time you execute PLOTBC the pen moves to the first row position on the paper. If the paper is already in the plotter, ignore the **INSERT PAGE** prompt and press **[R/S]**. The pen then moves to the first row position. If, when **INSERT PAGE** is displayed, you want to go to the main prompt without moving the pen, press ■ **[b]**. Likewise, if the HP-41 is set to any line in PLOTBC and is set to the User keyboard, you can go directly to the main prompt—and therefore bypass the **INSERT PAGE** prompt and any pen movement—by pressing ■ **[b]**.

Rows Per Page. When started from the top of an 8½ by 11-inch page and used without interruption, PLOTBC allows you to plot 13 standard HP-41 bar code rows to a page and prompts you when it is time to insert a new page. (If you plot data bar code, then shift to program bar code, a total of only 12 rows are plotted on the page.) If you have to insert a new page, press **[R/S]** when you are ready for bar code plotting to resume.

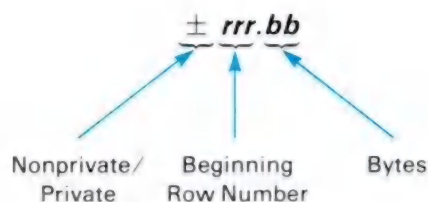

Changing Rows. Whenever the HP-41 is set to any line in the PLOTBC program, you can move the pen from the current row to the beginning of the next row by pressing ■ **[c]**. To move to the beginning of the preceding row, press ■ **[d]**. Whenever PLOTBC is in program memory, but the HP-41 is not set to any line in this program (for example, when it is set to one of the bar code subroutines), you can shift to the next row or the preceding row by executing **NXTROW** or **LSTROW**, respectively.

*Unless **PINIT** creates the I/O buffer. Refer to the last item in the list at the top of page 69.

Flags. PLOTBC uses the following HP-41 user flags: 9, 17, 22, 23, 27, and 29. The “numeric input” flag (flag 22) is used to detect your numeric data inputs for data bar code generation. This flag is not affected by data entered by recall from a storage register. Thus, if you enter Alpha or numeric data by recalling it from a storage register, then pressing $\boxed{R/S}$, the HP-41 responds as if no data was entered. (That is, it returns to the main prompt without plotting any bar code.)

Packing Memory. If a program you want to plot is not packed, PLOTBC automatically packs memory and prompts you to reexecute the program-plotting operation. Thus, if you want to avoid an interruption for packing, you should pack the HP-41's program memory before you begin plotting program bar code. (Refer to your HP-41 owner's manual.)

Program Bar Code Generation. The **ROW = 1.167** prompt allows you to accept or change the default beginning row and length parameters. (Default plotting begins with row 1. Default row length is 16 bytes—the maximum allowed.) The format to use for keying in your own starting row number and byte parameter is:

PLOTBC uses the absolute value of *rrr.bb* to determine row and byte length parameters. A negative *rrr.bb* value results in “private” program bar code. (A private bar code program can be scanned and executed like any other bar code program. However, a private bar code program cannot be viewed, listed, altered, recorded, or replotted through normal operations.)

Row Parameters. When you want to begin plotting program bar code at row 1, but do not want to print the program's name, key in zero for *rrr*. (An *rrr* of 0 defaults to 1 for purposes of selecting the starting row number.) If you select an *rrr* other than 0 or 1, there will be a pause between the moment you press $\boxed{R/S}$ to begin plotting bar code and the moment that the plotter actually begins plotting. This is because the system cannot start plotting at the row you want until it has computed the bar code checksums for all rows that precede the desired row.

Byte Parameters. Byte parameters of 00 through 04 and byte parameters exceeding 16 default to 16. Always key in byte parameters as two-digit numbers (05, ..., 16).

Halting Bar Code Generation. If, for any reason, you want to halt a bar code operation that is already underway, press the $\boxed{R/S}$ key. The plotter halts and lifts the pen. If you use this method to halt bar code generation, but want to continue the operation at a later time, you should resume by replotting the row that precedes the one in which you halted. This procedure helps to avoid a possibility of error in your desired bar code sequence.

Note: If you halt the system while a row of bar code is being plotted, the HP-41 will be set to the XBC program instead of to PLOTBC. Thus, to subsequently move to the next row position, you will have to execute NXTROW instead of pressing \boxed{C} . To move to the last row position you will have to execute LSTROW instead of pressing \boxed{d} .

Bar Code Subroutines

The bar code subroutines in the XBC program are provided for use in conjunction with PLOTBC when you want to plot several consecutive, left-justified rows of bar code on a page. However, you can also use these subroutines when you want to plot isolated rows of bar code at various positions on a page. To use any of the subroutines, enter the XBC program into your HP-41, use a plotter module function such as \boxed{MOVE} or \boxed{IMOVE} to position the pen, and execute the desired subroutine.

Note: The bar code subroutines use UUs to position bar code rows relative to their labels. For this reason, initialize your plotter to its default graphic limits and plotting area parameters before you use the bar code subroutines. An easy way to perform this operation is to turn your plotter off, then on, and execute `PINIT`.

General Operating Parameters

When you execute any of the bar code subroutines:

- Plot direction resets to 0°.
- Label direction resets to 90°.
- The current `CSIZE` or `CSIZE0` setting determines the character size for labels. (The `PINIT` default of 3 GUs is convenient for many applications.)
- Pen 2 prints the labels.
- Pen 1 plots the bar code, then returns to its stall.

When you execute a bar code subroutine, the label is printed at the last pen position specified by a plotter module function. The bar code row is plotted 2 UUs below the label. The default bar code height is 350 APUs. (You can change the height value using the `BCSIZE` function described under Changing the Bar Code Size and Type on page 111.)

Numeric data labels always contain all digits of the bar code they identify, and they are not affected by the current display setting.

Use of Registers

The bar code subroutines affect the stack and LAST X registers in various ways that are described separately below for each subroutine. The subroutines also use various bar code functions (described later in this section, beginning on page 127) that replace the contents of the ALPHA register with bit string data used to control bar code printing. If you set your HP-41 to Alpha mode after executing a bar code subroutine, you will see most of this bit string data displayed as nonstandard, unintelligible characters.

In most cases, the values remaining in the stack and LAST X registers after bar code subroutine execution are of no interest to the user.

X-Register Data Bar Code Subroutines

The following two subroutines generate numeric or Alpha bar code from corresponding data in the X-register. Both subroutines alter flag 29 (the digit grouping flag) and the display setting so that numeric data labels contain all significant digits of the value in the X-register. Alpha data strings in the X-register and their corresponding labels can contain up to six characters. (For most Alpha data applications, you will probably want to use the Alpha data bar code subroutines—described under the next heading—instead of the X-register data bar code subroutines.)

Note: The bar code subroutine examples on the following pages assume that you have executed `PINIT` and that the plotter module is set to your plotter's default graphic limits and plotting area.

XBC

X `data (Numeric or Alpha)`

The XBC (*Data Bar Code from X*) subroutine plots and labels a row of data bar code containing the data currently in the X-register. XBC labels always begin with a **D**: followed by the number or Alpha characters contained in the corresponding bar code. Scanning a row of numeric data generated by XBC

enters that row's data in the X-register. Scanning a row of Alpha XBC data replaces the contents of the ALPHA register with the Alpha data contained in the Alpha XBC row and switches the HP-41 to the Alpha keyboard.

Following XBC execution, the X-register indicates the number of bytes generated (and, for numeric data, the number of fractional digits). The Y-register contents remain unchanged. The Z- and T-registers contain variables produced during subroutine execution. The LAST X register contains a copy of the data plotted in bar code by XBC.

Example. Plot on the same line a row of numeric data and a row of Alpha data.* (This example assumes you have entered the XBC program from the bar code on page 207 or the program listing on page 171.)

Keystrokes	Display

(Keep the current page in your plotter for the next example.)

D: 1. 23456

D: "SAMPLE"

XSBC

Y	sequence number
X	data

The XSBC (*sequential data bar code from X*) subroutine plots and labels a row of sequential data bar code containing the data currently in the X-register. XSBC labels always begin with **SD n**: followed by the number or Alpha characters included in the corresponding bar code. To scan a row of bar code generated by XSBC, first execute the HP 82153A Optical Wand's [WNDTDX] function, then scan the sequential data rows in their proper order. The data in each scanned row is placed in the appropriate data storage register. (Refer to the [WNDTDX] function in the *HP 82153A Wand Owner's Manual*.) A sequence number greater than 999 results in a **NONEXISTENT** error message *after* the row label is printed.

Following XSBC execution, the X-register contains the *next* sequence number in the series. The value in the Y-register indicates the number of bytes generated. The Z- and T-registers contain variables produced during subroutine execution. The LAST X register contains a copy of the data printed in bar code by XSBC.

*Use the default parameters as described in the first note on page 121.

†For [ASTO], refer to the Alpha Keyboard illustration on the back of the HP-41.

Example. On the same line plot two rows of sequential numeric data bar code from X and one row of sequential Alpha data bar code from X. Use the default plotting parameters as described in the note at the top of page 121. (This example assumes you have entered the XBC program from the bar code on page 207 or the listing on page 171.)

SD 2: 1.732

SD 3: "X-SEQ"

Alpha Register Data Bar Code Subroutine

ABC

ALPHA Alpha data

The ABC (*Alpha data bar code*) subroutine plots and labels a row of Alpha data bar code containing the first 14 characters in the ALPHA register.* Any characters beyond the 14th character will be truncated (deleted from the ALPHA register). ABC labels always begin with A: followed, within quotation marks,

*Standard HP-41 Alpha characters as indicated on the HP-41's back label. (There are four exceptions, which are indicated in the chart on page 94.) Trailing nulls and nulls enclosed by Alpha characters will be printed in the bar code, but not in the corresponding label.

by the Alpha characters included in the corresponding bar code. Scanning a row of ABC bar code replaces the current contents of the ALPHA register with the scanned data and switches the HP-41 to the Alpha keyboard.

Following ABC execution, the X-register contains the number of bytes generated. The Y-, Z-, T-, and LAST X registers contain variables produced during subroutine execution.

Example: Place an Alpha string in the ALPHA register and plot a row of bar code containing this data. Use the default plotting parameters as described in the note at the top of page 121. (This example assumes you have entered the XBC Program from the bar code on page 207 or the listing on page 171.)

Keystrokes	Display	
ALPHA TEST SPACE	TEST _	} Enters the Alpha data in the ALPHA register.
ROW ALPHA	0.0000	
1 ENTER↑ 39 MOVE	39.0000	Positions pen for next row.
XEQ ALPHA ABC ALPHA	12.0000	Plots Alpha data bar code from data you entered in the ALPHA register.
0 PEN	0.0000	Returns pen to stall.

(Leave the current page in your plotter for the next example.)

A: "TEST ROW"

AABC

ALPHA Alpha data

The AABC (*Alpha-append bar code*) subroutine operates in the same way as the ABC subroutine, except that the bar code generated by AABC is in the Alpha-append format. (That is, scanning a row of AABC bar code appends the scanned data to the contents of the ALPHA register and switches the HP-41 to the Alpha keyboard.)

Generating Individual Rows of Program Bar Code

When you want to plot the bar code for an entire program, or from a particular row to the end of the program, you can use the PLOTBC program described under Using PLOTBC on page 115. However, when you want to plot a single program row or several rows without being restricted to a sequential row order, you can do so using PBC.

PBC

Y	program name
X	rrr.bb

The PBC (*program bar code*) subroutine plots and labels row *rrr* of the program named in the Y-register. *bb* determines the number of bytes in the row. PBC then increments *rrr* by 1 and halts. The program name remains in the Y-register. Thus, by using the data remaining in the X- and Y-registers after executing

PBC, you can print the next sequential program row by simply reexecuting PBC. You can select a random row by changing the *rrr* value in the X-register after PBC execution halts. PBC indicates that it has printed the last row in a program by replacing *rrr.bb* with 0.0000. As with the PLOTBC Program, before you use PBC to plot program bar code, you should pack the program by executing **█** **GTO** **00**.

For programs plotted in bar code it is usually preferable to use the same byte parameter—*bb*—for each row. The topic of row length is discussed on the next page, under The Row and Byte Parameters.

PBC uses data storage registers R₀₀ and R₀₁ to temporarily store the pen's location when you execute PBC. The contents of the Z-, T-, and LAST X registers are altered by variables produced during PBC execution.

The PBC subroutine switches the display setting to **FIX** 3.

Example: Plot a pair of sequential 10-byte rows and a nonsequential 10-byte row from the SET program used earlier in this manual. If SET is not currently in your HP-41, you can enter it using either the bar code listing on page 205 or the annotated listing on page 76. (This example assumes you have entered the XBC program from the bar code on page 207 or the listing on page 171, and that you are using the default parameters described in the note at the top of page 121.)

Keystrokes	Display	
1 ENTER 51 MOVE	51.0000	Positions pen for next row.
ALPHA SET █ STO	ASTO _	} Enters SET in X.
0 X ALPHA	SET	
2.10	2.10 _	Specifies row 2 and 10 bytes in X and lifts SET to Y.
XEQ ALPHA PBC	PBC _	Plots and labels a 10-byte version of row 2.
ALPHA	3.100	After plotting row, PBC automatically increments row counter by 1. SET remains in the Y-register.
1 ENTER 63 MOVE	63.000	Positions pen for next row.
R ↓ R ↓	3.100	Returns row parameters to X- and Y-registers.
XEQ ALPHA PBC	PBC _	Plots and labels a 10-byte version of row 3.
ALPHA	4.100	Increments row counter by 1.
1 ENTER 75 MOVE	75.000	Positions pen for next row.
R ↓ R ↓	4.100	Returns program label to Y-register and row parameter to X-register.
← 8.1	8.1 _	Switches row parameter from 4 to 8 and maintains same byte length (10).
XEQ ALPHA PBC	PBC _	Plots and labels row 8. Because last program line occurs before size specified for row (10 bytes) is reached, the row is less than 10 bytes long.
ALPHA	0.000	Indicates completion of the last row of the program.
█ FIX 4	0.0000	

Note: Because the rows generated by this example do not begin with row 1 and are, in the case of row 8, nonsequential, a checksum error message is generated when you attempt to scan these rows. To bypass a checksum error that results from scanning a row that is not in the numeric sequence expected by the wand, press **SST** one or more times, as needed, until the number of the row you want to scan is displayed. (Refer to Recovery: Program bar code, under **W:CKSUM ERR** in appendix A of the HP 82153A Wand Owner's Manual.)

ROW 2: LINES 2-5

ROW 3: LINES 6-10

ROW 8: LINES 26-28

Computation Time. When using PBC, if the first row you plot is not row 1, or if the rows you select are not sequential, several seconds or more may elapse between the time you execute PBC and when the plotter begins plotting the selected row. This is because the system must compute the checksums* for all preceding rows in order to determine the running checksum for the row you want to plot. For this reason, if you generate a series of nonsequential bar code rows, you should proceed from the lowest-numbered to the highest-numbered row.

The Row and Byte Parameters. The row number (*rrr*) and byte length (*bb*) conditions used by the PBC subroutine are identical to those described for printing PLOTBC program bar code.† If you specify “private” bar code by using a negative *rrr.bb* value, *rrr* is decremented when you execute PBC. If the absolute value of *rrr* exceeds the number of rows computed by the module for the program named in the Y-register, no plotting takes place. Instead, PBC replaces the *rrr.bb* value in the X-register with a zero and enters a zero in the Y-register. (The program name is lifted to the Z-register.)

When you are using PBC to generate a series of rows, you can vary the length of successively higher-numbered rows by changing the byte parameter (*bb*) between generation of any given row and the succeeding row.

Note: When plotting rows of program bar code in nonsequential order, you can plot rows numbered lower than rows you have already plotted as long as you do not change the number of bytes per row. When plotting rows in sequential order, you can change the byte length for rows that have not yet been plotted. However, if you wish to change the number of bytes for rows you have already plotted or rows numbered lower than other rows that you have already plotted, you must replot all rows in the program. Otherwise a checksum error will result when you scan the rows. This is because the checksum for any row is based on the running checksum accumulated for all sequentially earlier rows in the program (even if those rows have not actually been plotted).

The Program Name Parameter. A number or an Alpha null string (a string of blank Alpha characters) used in the Y-register instead of a program name specifies the last program in HP-41 memory. (If you pack program memory by pressing **▀** **GTO** **▢** **▢** after entering the last program in memory, the permanent **•END•** placed at the end of memory by **▀** **GTO** **▢** **▢** becomes the “last program.”)

*The system always maintains the running checksum computed to the last row specified by execution of PBC. Thus, if you print any series of rows in ascending order, the system has only to compute the running checksum from the last row specified by PBC to the next row specified by the next successive execution of PBC. If any two successive executions of PBC result in a descending order of row numbers, the system must recompute the running checksum from the beginning of the program, which means added calculation time.

†Refer to the information on page 120 under the following three headings: Program Bar Code Generation, Row Parameters, and Byte Parameters.

Editing and Packing a Program Between Executions of PBC. You can edit any line in a program only if that line comes later in memory than the last row plotted. When you do so, execute **PACK** or **GTO** to pack program memory before you resume generating bar code. If you edit a part of a program that is within or prior to the highest-numbered row already plotted, you must plot the row containing the edited material and all subsequent rows. Otherwise, the running checksum will be in error for all rows numbered higher than the row containing the edited material.

When you execute PBC, if the program you specify is not already packed, the HP-41 packs the program. (Refer to the **PACK** function in your HP-41 owner's handbook.) If this occurs, simply reexecute PBC when **TRY AGAIN** is displayed.

Basic Bar Code Functions

The following text describes the bar code functions used by PLOTBC and the bar code subroutines. Using these functions to generate bar code is a two-step process. The first step determines and stores in the ALPHA register a bit pattern for the desired row. The second step plots the row at the current physical pen position (or prints the row if the HP 82162A Thermal Printer is being used with the plotter module). The basic bar code functions do not generate labels for bar code rows.

Learning How to Plot or Print Bar Code

Five of the next six functions described in this section are used to generate both plotter and printer versions of HP-41 bar code. The examples provided with the descriptions of these functions apply to plotter operation. Examples that use these functions for printer operation are provided later, under Printing HP-41 Bar Code on the HP 82162A Thermal Printer. Thus, if you are using a plotter, you can read through the descriptions and perform the examples in the same way that you have done elsewhere in this manual. If you are using an HP 82162A Thermal Printer to generate bar code, you should read the function descriptions (except that for **BC**) but can ignore the plotter examples.

Setup for Examples

Before you use the bar code functions with your plotter, ensure that there is sufficient space in the plotting area to print the bar code. The easiest way to do this is to set the default graphic limits by turning your plotter off, then on, and executing **PINIT**. The following keystrokes set up the plotter system for subsequent examples in this section.

Keystrokes	Display	
PINIT	0.0000	Initializes plotter module.
0 PEN	0.0000	Returns pen to stall.
■ FIX 4	0.0000	Sets display mode to FIX 4.

Standard HP-41 Data and Program Bar Code

BC

ALPHA bit pattern

The **BC** (plot standard HP-41 barcode) function uses the bit pattern placed in the ALPHA register by the next five functions (**BCX**, **BCXS**, **BCA**, **BCAA**, or **BCP**) to plot a single row of HP-41 data or program bar code. When **BC** plots the row, it plots the standard HP-41 directional bars at the beginning and end of the row.

BC does not alter the contents of the stack, ALPHA, or LAST X registers. (The descriptions of the following five functions include examples of **BC** operation.)

Depending on pen width, **BC** can plot bar code rows having up to 128 bars (16 bytes), which is the maximum row length for HP-41 applications.

The **BC** function also plots HP-41 paper keyboard and direct execution bar code. Generating these two types of bar code requires more advanced bar code techniques, which are discussed later in this section.

BCX**X** **data****Numeric or Alpha**

The **BCX** (*bar code for data in X*) function places in the ALPHA register a bit pattern for nonsequenced bar code representing the data in the X-register. Following **BCX** execution, the X-register shows the number of bytes in the bit pattern. The LAST X register contains a copy of the data originally in the X-register. The contents of the Y-, Z-, and T-registers are unaffected. Alpha data is limited by the X-register to a maximum of six characters and is printed as Alpha-Replace (type 7)*† bar code. Numeric data is printed as numeric data (type 6)† bar code.

Example: Place a fresh page in your plotter and generate one row each of numeric and Alpha data bar code for the X-register. Use **BCX** to create the bit patterns and use **BC** to actually generate the bar code. (This example assumes that the graphic limits and plotting area are set as described under Setup for Examples on page 127.)

Keystrokes**Display**45 **SIN**

0.7071

Places data in X.

BCX

7.0000

Places bit pattern for 0.7071‡ in ALPHA and replaces data in X with a value indicating the number of bytes in the bit pattern.

ALPHA

888788

Displays bit pattern placed in ALPHA by **BCX**.**ALPHA**

7.0000

Returns display to X.

1 **PEN**

BC

15.0000

Generates row of Alpha data bar code from bit pattern in ALPHA.

0 **PEN**

0.0000

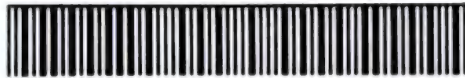

Returns pen to stall.

(Leave the current page in your plotter for the next example.)

*When you scan a row of Alpha-Replace bar code, the data contained in the row replaces the current contents of the ALPHA register.

†You can ignore the type number unless you need to use the utility bar code functions described later in this section and the charts in appendix F to design the byte structure of bar code for specialized applications.

‡Because the HP-41 computes this value to nine fractional digits—five of which are not displayed due to the current **FIX** 4 display setting—the actual number coded in the bit pattern contains nine fractional digits.

Note for Advanced Users: When required, **BCX** automatically places *filler bits*—1010—at the beginning of numeric bar code bit strings. (Filler bits are required if the data in the X-register produces a bit pattern that is not a multiple of 8 bits.)

BCXSY **sequence number** $0 \leq s \leq 999$ X **data**

Numeric or Alpha

The **BCXS** (*sequenced bar code for data in X*) function places in the ALPHA register a bit pattern for sequenced bar code representing the data in the X- and Y-registers. Following **BCXS** execution the X-register contains a value indicating the number of bytes in the bit pattern. The Y-register contains the *next* sequence number in the series. The LAST X register contains a copy of the data originally in the X-register. The Z- and T-registers are unaffected.

Note: **BCXS**-generated bar code is designed to be scanned by revision F and later versions of the HP 82153A Optical Wand. The first marketed version of the wand was revision E. There is no functional difference between revisions E and F except the addition of the sequenced data bar code type. To determine the revision letter of your wand, remove all modules from your HP-41, then plug in the wand and press **■ CATALOG 2**. The revision letter will appear in the display. Attempting to read sequenced data bar code with a revision E wand results in a **TYPE ERROR** or improper operation that includes nonstandard data.

Example: Generate two rows of numeric data bar code that you can store sequentially in your HP-41's data storage registers. (This example uses the plotting area established by the keystrokes under Setup for Examples on page 127.)

Keystrokes**Display**1 **PEN**

1.0000

Selects pen 1.

10 **ENTER** 25 **MOVE**

25.0000

Generates row of numeric-sequential data bar code from bit pattern in ALPHA.

xzy

1.0000

Displays incremented sequence number.

60 **COS**

0.5000

Enters data in X and lifts sequence number to Y.

*Refer to the third footnote on page 128.

Keystrokes	Display	
BCXS	4.0000	Places bit pattern for 0.5000 in ALPHA, increments sequence number in Y, and replaces data in X (0.5000) with size of bit pattern.
10 ENTER 35 MOVE	35.0000	Moves pen to next position.
BC	35.0000	Generates row of numeric-sequential data bar code from bit pattern in ALPHA.
R R R	2.0000	Displays incremented sequence number.
0 PEN	0.0000	Returns pen to stall.

(Leave the current page in your plotter for the next example.)

When you want the data from **BCXS**-generated bar code to be stored in a series of data storage registers, use the wand's **WNDDTX** function. When you want such data placed in the X-register, simply scan the bar code.

Alpha Data Bar Code Functions

BCA

ALPHA Alpha data

The **BCA** (*Alpha-Replace bar code*) function converts the current data in the ALPHA register to an Alpha-Replace bar code bit pattern. If there are more than 14 characters in ALPHA when you execute **BCA**, only the last 14 are used. (If the ALPHA register contains only nulls, **BCA** generates a row of bar code containing a two-byte header and a one-byte null string.) **BCA** also copies the X-register value into LAST X and places in X a value indicating the number of bytes in the bit pattern. The contents of the Y-, Z-, and T-registers are unaffected. Scanning **BCA**-generated bar code replaces the contents of the ALPHA register with the ALPHA data in the bar code.

Example: Generate a row of Alpha-Replace bar code. (This example uses the plotting area established by the keystrokes under Setup for Examples on page 127.)

Keystrokes	Display	
1 PEN	1.0000	Selects pen 1.
15 ENTER 45 MOVE	45.0000	Moves pen to next row position.
ALPHA YOUR SPACE	YOUR _	Places data in ALPHA.
DATA ALPHA	45.0000	
BCA	11.0000	Replaces data in ALPHA with corresponding bit pattern, and replaces contents of X with size (bytes) of bit pattern.
BC	11.0000	Generates a row of Alpha-Replace bar code from bit pattern in ALPHA.
0 PEN	0.0000	Returns pen to stall.

(Leave the current page in your plotter for the next example.)

BCAA

ALPHA alpha data

The **BCAA** (*Alpha-Append bar code*) function operates in the same way as the preceding **BCA** function. However, scanning **BCAA**-generated bar code appends the data contained in the bar code to the current contents of the ALPHA register instead of replacing the contents.

Program Bar Code Function

BCP

Y	program name
X	± rrr.bb

The **BCP** (*program barcode*) function generates for row *rrr* of the program specified in the Y-register a bar code bit pattern *bb* bytes in length. A negative *rrr.bb* value specifies “private” bar code. The absolute value of the current *rrr* is then incremented to the next sequential row number. The numbers of the first and last program lines included in that row are placed in the Z-register in an *ff.fff* format (includes lines carried over from the last row or to the next row). The number of bytes generated in the bit pattern is placed in the T-register.

T	bb	ALPHA Bit Pattern
Z	ff.fff	
Y	Program Name	
X	± rrr.bb	

If *rrr* specifies the last row of the program, **BCP** replaces *rrr.bb* with zero. If *rrr* specifies a nonexistent row, **BCP** places zeroes in the X-, Z-, and T-registers, and places a one-byte null string in the ALPHA register. The program name remains in the Y-register.

As with the PLOTBC program and the PBC subroutine, before you use **BCP** to generate a program row bit pattern, you should first pack the program by executing **█ GTO █ █**.

Example: Plot, one by one, the rows of program bar code for the TERM program used earlier in this manual. (If this program is not currently in your HP-41, you can load it using the bar code on page 205 or the annotated listing on page 77.)

Keystrokes

```
1 PEN
5 ENTER ↑ 60 MOVE
ALPHA TERM █ ASTO
█ X ALPHA
1,11
```

Display

```
1.0000
60.0000
ASTO --
TERM
1.11 --
```

Selects pen 1.

Positions pen for next row.

Places program name in X.

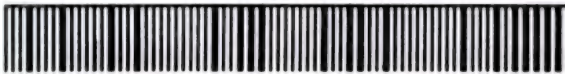

Enters *rrr.bb* in X and program name in Y.

You are now ready to execute **BCP** to generate in the ALPHA register the bit pattern for the first row. When you do so, the stack will contain the values described and illustrated on the preceding page.

Keystrokes	Display	
BCP	2.1100	Generates in ALPHA the bit pattern for row 1 of TERM program. Displays next row number and row length.
R↓	TERM	Rolls down stack to show program label from Y-register.
R↓	1.0010	Rolls down stack to show data from Z indicating bit pattern contains data for program line 1.
R↓	11.0000	Rolls down stack to show data from T indicating there are 11 bytes in the bit pattern.
R↓	2.1100	Rolls down stack to return data for next row to X. (All values returned to their original stack registers.)

Now plot the bar code for row 1 from the bit pattern currently in the ALPHA register by executing **BC**. Then reexecute **BCP** as needed to generate in the ALPHA register the bit patterns for rows 2 and 3. Because row 3 is the final row of the TERM program, **0.0000** will be displayed to indicate that no higher-numbered rows can be generated for this program. Also, because this last row does not require a full 11 bytes to complete the program, the T-register will contain a number indicating fewer than 11 bytes.

Keystrokes	Display	
BC	2.1100	Plots row 1 of TERM program. Does not affect display or any values in the stack.
5 ENTER↑ 70 MOVE	70.0000	Positions pen for next row. Values remaining in Z and T for row 1 bit pattern are lost.
R↓ R↓	2.1100	Rolls down <i>rrr.bb</i> and program name to X and Y, respectively.
BCP	3.1100	Generates in ALPHA the bit pattern for row 2 of TERM program. Displays next row number and row length.
R↓	TERM	Program label remains in stack.
R↓	2.0060	Indicates that bit pattern for this row contains data for program lines 2 through 6.
R↓	11.0000	Indicates that bit pattern contains 11 bytes.
R↓	3.1100	Returns all values to their original stack registers.
BC	3.1100	Plots row 2 of TERM program.
5 ENTER↑ 80 MOVE	80.0000	Positions pen for next row.
R↓ R↓	3.1100	Rolls down <i>rrr.bb</i> and program name to X and Y.
BCP	0.0000	Generates in ALPHA the bit pattern for row 3 of TERM program. Displayed zeroes indicate that row 3 bit pattern contains the program's last row.
BC	0.0000	Plots program's last row.
PEN	0.0000	Returns pen to stall.

BCP is used in the PBC subroutine described on page 124. Thus, **BCP** uses parameters in the same way as PBC and generates single rows in a manner similar to that of PBC and to the program bar code aspects of PLOTBC—which itself uses PBC.

To generate bit patterns for random rows, change the *rrr* portion of the *rrr.bb* value remaining in the X-register after each execution of **BCP**. This feature is useful if you have to replot a row that was damaged or plotted with a pen having a depleted ink supply.

When printing nonsequential program bar code rows, the time considerations are the same as those described under Computation Time on page 126.

Printing HP-41 Bar Code on the HP 82162A Thermal Printer

The HP 82184A Plotter Module enables you to print any type of HP-41 bar code on an HP 82162A Thermal Printer. To print bar code, you need only your HP-41, the plotter module, and the following three items:

- HP 82162A Thermal Printer.
- HP 82175A Black Print Thermal Paper.
- HP 82160A HP-IL Module.

To print most types of HP-41 bar code, use the basic bar code functions described earlier in this section (pages 127 through 133) and the printer option of the **BCO** function described following this introductory information. To see how easy it is to print bar code, connect your HP-41 and printer to the interface loop, place a roll of black thermal paper in the printer, and step through the following example. (This example is intended to demonstrate the plotter module's bar code printing capability rather than instruct in how to print bar code. The material following the example describes the details of bar code printing.)

Note: Unless you are printing program bar code, the I/O buffer is not used for bar code printing operations on the HP 82162A Thermal Printer. This topic is described on the next page, under Using **BCO** to Print Standard HP-41 Program Bar Code.

Bar Code Printing Example. Print a row of numeric data bar code containing the approximate speed of light in a vacuum (kilometers/second) and a row of Alpha data bar code containing the characters "HP-41 bar code".

Keystrokes

Keystrokes	Display	
BAR SPACE CODE	41 BAR CODE _	
ALPHA	-6.0000	
BCA	16.0000	Replaces characters in ALPHA with a bit pattern containing the characters. Places in X the number of bytes in the bit pattern.
CHS	-16.0000	Converts byte value to a negative number.
BCO	-16.0000	Prints a row of bar code containing the characters "HP-41 BAR CODE".

As you can see, printing bar code on the HP 82162A Thermal Printer is a short, quick procedure. Now let's learn more about the **BCO** function you used in the preceding example to print the bar code.

Using **BCO** to Print Standard Data and Program Bar Code

The **BCO** function provides you with a *printer option* for printing HP-41 bar code, and a *plotter option* for plotting both HP-41 bar code and non HP-41 bar code. The following material describes how to use the **BCO** function's printer option to print standard HP-41 data and program bar code.

BCO (Printer Option) X -bb ALPHA bit pattern

Executing the printer option of the **BCO** (*bar code options*) function prints on the HP 82162A printer a row of HP-41 bar code corresponding to the bit pattern in the ALPHA register. The absolute value of the negative number in the X-register ($|-bb|$) tells **BCO** how many bytes of HP-41 bar code to print. The value $|-bb|$ must be in the range $1 \leq |-bb| \leq 16$.

Using **BCO to Print Standard HP-41 Data Bar Code.** The four data bar code functions (**BCX**, **BCXS**, **BCA**, and **BCAA**) described on pages 128 through 133 each place a bit pattern in the ALPHA register and the number of bytes (**bb**) for the bit pattern in the X-register. After you execute one of these functions to generate the bit pattern and number of bytes, perform the following two steps to print on the HP 82162A Thermal Printer the row of bar code corresponding to that bit pattern:

1. Change the byte number (**bb**) in the X-register to a negative value by executing **CHS**.
2. Execute **BCO**.

The preceding example demonstrates how to use this procedure.

Using **BCO to Print Standard HP-41 Program Bar Code.** The **BCP** function described on pages 131 through 133, generates the data used by **BCO** to print program bar code. Since **BCP** uses the I/O buffer (described on pages 10 and 11), create the buffer by executing **PINIT** before you use **BCP**. *Unless a plotter is plugged into the interface loop, you must set flag 25 (the Error Ignore flag) before executing **PINIT**.* Otherwise, the **NO PLOTTER** message appears and the buffer will not be created.

To generate on the HP 82162A Thermal Printer a row of program bar code:

1. Generate a bit pattern for the desired row by executing **BCP**.
2. Recall from the T-register the byte number (**bb**) generated by **BCP**.
3. Change **bb** to a negative value by executing **CHS**.
4. Execute **BCO**.

Printed Program Bar Code Example. Print the bar code for the TERM program listed on page 77 of this manual. (If the TERM program is not currently in your calculator, enter it before you proceed with this example.)

Prints last row of bar code.

Clears display.

Note: When you execute **BCO** to print a row, if you use for *-bb* a value other than that computed by that row's basic bar code function, the resulting bar code may be unreadable or interpreted incorrectly by the wand. That is, if $\text{INT}|-bb|$ is not equal to the number of bytes in the ALPHA register when you execute **BCO**, the length of the printed row will not correspond to the number of bytes in ALPHA. Because the checksums in such rows are not likely to correspond to the printed bit pattern, the wand will usually not read such rows except under control of the **WNDSCN** or **WNDTST** functions. However, if such a row should correspond to the bit pattern of any legitimate bar code other than that specified in the ALPHA register, the row will be readable without executing **WNDSCN** or **WNDTST**. Except under controlled operating conditions, this could introduce an error that would not be detected by the HP-41. If there are more than $|-bb|$ bytes of data in the ALPHA register, only the last $|-bb|$ bytes will be printed.

Applications Program for Printer-Generated Program Bar Code. The PRBC program included in this manual prompts you for the name of a program you have entered in the HP-41's memory, then prints the bar code for that program (including row labels). PRBC limits bar code row length to nine bytes so that the rows can be conveniently mounted on standard 8½-inch pages. For a listing and description of PRBC, refer to pages 172 and 173. Bar code for PRBC is on pages 202 and 203.

Printing Paper Keyboard and Direct Execution Bar Code

HP-41 paper keyboard and direct execution bar code is printed using the printer option of the **BCO** function in the same way that it is used for printing HP-41 data and program bar code. However, determining the bit pattern for paper keyboard and direct execution bar code is a more complex process that involves the use of appendix F, Bar Code Charts, and execution of the **BCREGX** and **BCCKSM** functions, which are described next.

Utility Bar Code Functions

The utility bar code functions enable you to plot paper keyboard and direct execution bar code. They also give you the flexibility to plot specially designed HP-41 bar code (used with **WNDSCN**) and design alternative bar code for devices used in other scanning systems.

The bar code functions described in the following text involve, on the user level, some of the more technical aspects of bar code generation. For this reason you may need more time to study these functions than was necessary for the bar code functions described earlier.

In the following discussion, "first byte" always refers to the leftmost byte displayed in the ALPHA register; the "last byte" refers to the rightmost byte.

Generating the Bit Pattern and Checksum Separately

The following two functions are designed for plotting HP-41 paper keyboard and direct execution bar code, but can also be used to plot non HP-41 bar code rows.

BCREGX

X **iii.fff**

The **BCREGX** (*bar code from registers according to X*) function transforms the values in the specified storage registers to characters in the ALPHA register. These characters hold the bit patterns which correspond to the values in those registers. The leftmost character holds the bit pattern for the value in the lowest numbered register (**iii**), and the rightmost character holds the bit pattern for the value in the highest numbered register (**fff**). **BCREGX** uses the control value in the X-register, **iii.fff**, to build bit patterns in the ALPHA register corresponding to the values in registers **iii** through **fff**.

- If **fff** > 0, **BCREGX** uses the data in R_{iii} through R_{fff} .
- If **fff** = 0, **BCREGX** uses the data in R_{01} through R_{iii} .
- If **iii** > **fff**, **BCREGX** uses only the data in R_{iii} .
- If **iii** = 0 and **fff** > 0, then **BCREGX** uses the data in R_{00} .

Each value in a data register corresponds to one byte in the bit pattern. Since these values are converted to eight-bit binary code in ALPHA, the values you use with **BCREGX** must be in the range 0 through 255. (Fractional portions of values in the data registers are ignored.) Unlike the bar code generation functions covered earlier, **BCREGX** does *not* generate a checksum for the bit pattern placed in the ALPHA register. The function described next, **BCCKSM**, is designed specifically for this purpose. Executing **BCREGX** does not alter the values currently in the stack.

Example: Using **BCREGX** with **BC**, plot a five-byte row of arbitrary HP-41 bar code. Then, if you have an HP 82153A Optical Wand, plug it into your HP-41, execute **WNDSCN**, and scan the row. (Because a bar code type and checksum are not included in this row, you will be able to read the row only by executing **WNDSCN** or **WNDTST**.) Before you begin, position the pen at a convenient location for plotting a row of five bytes.*

Keystrokes	Display

5 ENTER MOVE	5.0000	Moves pen to plotting position.
10 STO 06	10.0000	Stores 10 in R ₀₆ .
20 STO 07	20.0000	Stores 20 in R ₀₇ .
30 STO 08	30.0000	Stores 30 in R ₀₈ .
40 STO 09	40.0000	Stores 40 in R ₀₉ .
50 STO 10	50.0000	Stores 50 in R ₁₀ .
6.01	6.01 _	Specifies R ₀₆ as the initial (<i>iii</i>) register, and R ₁₀ as the final (<i>fff</i>) register.
BCREGX	6.0100	Places in ALPHA a bit pattern for the data you stored; one byte for each data register position.
BC	6.0100	Plots the data as HP-41 bar code.
0 PEN	0.0000	Returns pen to stall.
WNDSCN	W: READY	Prompts you to scan a row of bar code. (This step requires that a wand be plugged into your HP-41.)
(scan the row)	5.0000	Displays the number of bytes read.
RCL 01	10.0000	} Displays decimal equivalents of the five bytes in the scanned row.
RCL 02	20.0000	
RCL 03	30.0000	
RCL 04	40.0000	
RCL 05	50.0000	

(If you are continuing on to the next example, leave the current page in your plotter.)

Note: If there are more than 16 bytes of data in the ALPHA register, **BC** generates a bar code row containing only the last (rightmost) 16 bytes. (This is the maximum row length that the HP 82153A Optical Wand can read. However, you can use the plotter option of the **BCO** function—described later in this section—to generate alternate types of bar code containing up to 24 bytes in a row. Refer to Plotting Alternative (Non HP-41) Bar Code, page 143.)

BCCKSMX **bb**ALPHA **bit pattern**

The **BCCKSM** (compute bar code checksum) function computes the checksum of the bit pattern represented by the characters in the ALPHA register. To use **BCCKSM**, place the desired bit pattern in the ALPHA register (using **BCREGX**), key the number of bytes (**bb**) of that pattern into the X-register, and execute **BCCKSM**. **BCCKSM** computes the checksum for **bb** bytes and places it as a bit pattern in byte **bb** (counting from the right).

BCCKSM can be used with **BCREGX** and **BC** to plot HP-41 paper keyboard and direct execution bar code. (Other bar code functions, such as **BCX**, automatically include a checksum in the bit pattern.) However, you can also use **BCCKSM** with the plotter option of the **BCO** function (described later in this section) to plot non HP-41 bar code. Executing **BCCKSM** alters only the contents of the ALPHA register.

*To print the bar code from this example on the HP 82162A Thermal Printer, ignore the pen movement instructions and replace the **BC** function with the following keystrokes: 5 **CHS** **BCO**.

The value of **bb** placed in the X-register to produce standard HP-41 paper keyboard and direct execution bar code determines which of the following three types of checksum are calculated:

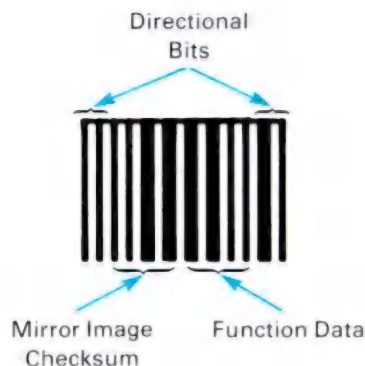

- Four-bit mirror checksum if **bb** = 1.
- Four-bit summation checksum with end-around carry if **bb** = 2.
- Eight-bit summation checksum with end-around carry if **bb** ≥ 3.

The type of checksum calculated depends upon the row length of the bar code you are generating.

Four-Bit Mirror Checksum

The four-bit mirror image checksum is normally used with one-byte paper keyboard bar code. The structure of this type of bar code is described in the One-Byte Paper Keyboard chart in appendix F, Bar Code Specification Charts.*

To specify the checksum for a one-byte paper keyboard bit pattern in the ALPHA register, place 1 in the X-register and execute **BCCKSM**. A mirror image of the rightmost four bits will be placed in the leftmost four bits as the checksum.

The four-bit mirror checksum is placed in the leftmost four bits of the rightmost byte in the ALPHA register.† (These four bits don't hold any other information essential to the paper keyboard function.)

Example: Plot the one-byte paper keyboard bar code for the HP-41 **CHS** function. To generate the **CHS** bit pattern, convert the binary representation of **CHS** (1100—found in the One-Byte Paper Keyboard Bar Code chart in appendix F) to its decimal value (12) and store it in R_{01} . Enter 1 into the X-register and execute **BCREGX**. Then, with 1 in the X-register to specify the four-bit mirror checksum, execute **BCCKSM**. To see the effect of **BCCKSM** on the bit pattern, plot the bit pattern both before and after you generate the checksum.‡

*This type is also described in section 1, Description of Bar Code Types, in *Creating Your Own HP-41 Bar Code*, part number 82153-90019. This Hewlett-Packard technical manual provides a base for generating HP-41 bar code on computer printer/plotter systems. For further information, contact your authorized Hewlett-Packard dealer. In the U.S.A., refer to Dealer and Product Information on page 159.

†Executing **BCCKSM** with 1 in the X-register always generates a four-bit mirror checksum for the rightmost byte, regardless of how many non-null bytes are currently in the ALPHA register.

‡To print the bar code from this example on the HP 82162A Thermal Printer, use the following keystrokes instead of those shown in the example: 12 **STO** 01 1 **BCREGX** **BCCKSM** **CHS** **BCO**. (Using a plotter for this example produces three rows; using a printer produces one row.)

Keystrokes	Display	
1 PEN	1.0000	Selects pen 1.
5 ENTER 15 MOVE	15.0000	Position pen to new row.
12 STO 01	12.0000	Stores decimal representation of CHS in R ₀₁ .
1 BCREGX	1.0000	Computes and stores in ALPHA a bit pattern representing the data in R ₀₁ .
0 ENTER ENTER	0.0000	
1 BCO	1.0000	Plots the bar code pattern before the checksum is calculated.
BCCKSM	1.0000	Calculates the four-bit mirror image checksum and inserts it into the existing pattern.
15 ENTER 15 MOVE	15.0000	Positions pen for next row.
0 ENTER ENTER	0.0000	
1 BCO	1.0000	Plots bar code for CHS bit pattern in the ALPHA register. The bar code has the checksum included, but has no directional bits.
25 ENTER 15 MOVE	15.0000	Positions pen for next row.
BC	15.0000	Plots bar code for CHS bit pattern in ALPHA with directional bits.
0 ENTER MOVE PEN	0.0000	Removes pen from plotting area.

(If you are continuing on to the next example, leave the current page in your plotter.)

The rows you plotted in the preceding example should look like this:

Note: If you use this type of checksum for bar code other than that described under One-Byte Paper Keyboard Bar Code on page 216 in appendix F, the checksum will not be correct. However, such bar code can be scanned using the **WNDSCN** function.

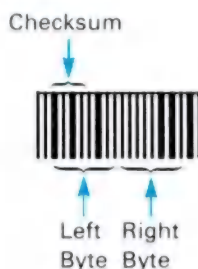

Four-Bit Summation Checksum

The four-bit summation checksum is normally used with two-byte paper keyboard bar code. The structure of this type of bar code is described in the Two-Byte Paper Keyboard chart in appendix F, Bar Code Specification Charts.*

Four-Bit Summation Checksum Procedure. To generate the checksum for a two-byte paper keyboard bit pattern in the ALPHA register, enter 2 in the X-register and execute **BCCKSM**. This creates a four-bit summation checksum (with end-around carry) that is placed in the leftmost four bits of the left byte.†

* Refer to the first footnote on page 138.

† **BCCKSM** calculates the checksum for the rightmost *bb* bytes in the bit pattern. For example, if there are five bytes in the ALPHA register and 2 (*bb*) is in the X-register when **BCCKSM** is executed, only the two rightmost bytes will be used for calculating the checksum. The checksum is then placed in the second (*bb*) byte from the right.

This type of checksum replaces the leftmost four bits in the leftmost byte with the checksum of the two-byte bit pattern. As with the four-bit mirror image checksum, the four-bit summation checksum replaces bits that, in functions included in the HP-41 paper keyboard, are zeroes.* If more than two bytes are in the ALPHA register, then the checksum will be placed in the second byte from the right. In such cases, the resulting HP-41 bar code can be read only by executing `WNDSCN` or `WNDTST`.

Note: The first byte should have a decimal value less than or equal to 15 to ensure that its leftmost four bits are 0. When you execute `BCCKSM`, these four bits are added into and replaced by the checksum. If these four bits are 0, the checksum is correct. If these four bits have some other value, the checksum will be incorrect.

The following two examples demonstrate how to plot two-byte paper keyboard bar code with four-bit summation checksums.

Example: Plot the bar code for the HP-41 `BEEP` function. From item 1 (A through C) in the Two-Byte Paper Keyboard chart in appendix F (page 216), zero is the value of the first byte. Usually the decimal value of the first byte should be stored in the first data register of the series. But since, in this case, the first byte is a null, it need not be stored.

Item 1D of the Two-Byte Paper Keyboard chart indicates that the second byte must contain the value (function code) of the particular function. The decimal value of the `BEEP` function is 134.* Key in this value and store it in R_{02} . Then key in 2.002 and execute `BCREGX` to generate the bit pattern in the ALPHA register.†

Keystrokes	Display	
1 <code>PEN</code>	1.0000	Selects pen 1.
5 <code>ENTER</code> 25 <code>MOVE</code>	25.0000	Positions pen for new row.
134 <code>STO</code> 02	134.0000	Stores 134 in R_{02} for the decimal equivalent of the rightmost byte in the bit pattern.
2.002 <code>BCREGX</code>	2.0020	Generates bit pattern in ALPHA from contents of R_{02} .
2 <code>BCCKSM</code>	2.0000	Calculates a four-bit summation checksum and adds it into the leftmost four bits of the left byte. (Prior to executing <code>BCCKSM</code> the left byte was an undisplayed null byte.)
<code>BC</code>	2.0000	Plots two-byte paper keyboard bar code for <code>BEEP</code> function.
0 <code>PEN</code>	0.0000	Returns pen to stall.

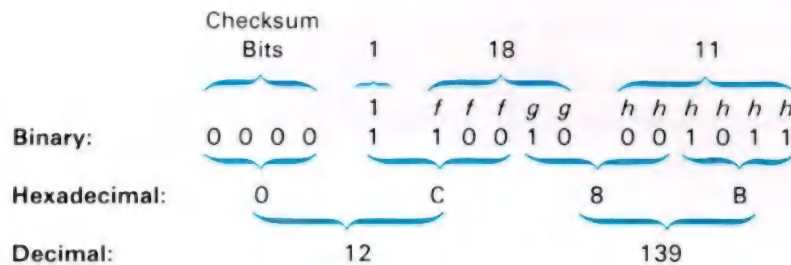

(If you are continuing on to the next example, leave the current page in your plotter.)

*Found in hexadecimal form in the HP-41 Function table on page 219. (The same table is also printed in section 4, Algorithms, in the *Creating Your Own HP-41 Bar Code* manual described in the first footnote on page 138.)

†To print the bar code from this example on the HP 82162A Thermal Printer, ignore the pen movement instructions and replace the `BC` function with the following keystrokes: `CHS` `BCQ`.

Example: Plot the bar code for the plotter module's **BC** function. As indicated under item 5 in the Two-Byte Paper Keyboard chart (page 216), you must first convert the **BC** function's XROM number (18,11—from the table on page 210) into a binary representation of the two-byte row you want to generate (using zeroes for the unknown checksum bits). You then convert this binary value into a pair of decimal values you can use with **BCREGX** to generate the necessary bit pattern in ALPHA. Before you begin, position the pen at a location convenient for plotting a two-byte row.*

**Keystrokes****Display**

1 PEN	1.0000	Selects pen 1.
5 ENTER 35 MOVE	35.0000	Positions pen for new row.
12 STO 01	12.0000	Stores 12 in R ₀₁ for the decimal equivalent of the left byte in the bit pattern.
139 STO 02	139.0000	Stores 139 in R ₀₂ for the decimal equivalent of the right byte in the bit pattern.
2 BCREGX	2.0000	Generates bit pattern in ALPHA from contents of R ₀₁ and R ₀₂ .
BCKSM	2.0000	Calculates four-bit summation checksum and adds it into the leftmost four bits of the left byte with a four-bit summation checksum.
BC	2.0000	Plots two-byte paper keyboard BC (XROM) function.
0 PEN	0.0000	Returns pen to stall.

(If you are continuing on to the next example, leave the current page in your plotter.)

*To print the bar code from this example on the HP 82162A Thermal Printer, ignore the pen movement instructions and replace the **BC** function with the following keystrokes: **CHS** **BCO**.

[BC] and Null Bytes

[BC] uses the leftmost non-null (nonblank) character in the ALPHA register as the leftmost data byte in a bar code row.* Thus, [BC] cannot produce a row in which the first byte is null. (In all but one case, standard HP-41 bar code has a non-null checksum in the first byte. The single exception is the one-byte row which the HP 82153A Optical Wand interprets as the paper keyboard zero value. To generate this row, clear the ALPHA register, then execute [BC].)

Eight-Bit Summation Checksum

A row of direct execution bar code contains three or more bytes plus an eight-bit summation checksum. This type of bar code is described in appendix F under Direct Execution Bar Code. When generating direct execution bar code, you may need to refer to one or more of the following three tables in appendix F:

- HP-41 Function Table.
- Numeric Values for A through J, a through e, X, Y, Z, T and L.
- Programmable Function Derivation.

Eight-Bit Checksum Procedure. To generate the checksum for a direct execution bit pattern of bb bytes, enter a value of $bb + 1$ in the X-register, then execute [BCCKSM]. This procedure inserts an eight-bit summation checksum as the leftmost byte in the bit pattern. Thus, to generate the checksum for a three-byte direct execution bit pattern, enter 4 in the X-register and execute [BCCKSM].

Example: Plot the direct execution bar code for the PLOTBC program described at the beginning of this section. Referring to the Direct Execution Bar Code chart on page 216, you can see that direct execution bar code rows include a checksum, type indicator (40_{16}), and a function code. The function code must include the [XEQ] α function and the Alpha characters PLOTBC. Thus, the desired bit pattern's components are:

Checksum	Type	Unused	[XEQ] α	PLOTBC
8 bits	4	0	8 bits	48 bits
Byte 1	Byte 2		Byte 3	Bytes 4 through 9

The checksum is computed last. The type indicator in the second byte is 40_{16} , or 64_{10} . The remainder of the bit pattern can be computed using row 1 of the Programmable Function Derivation chart on page 218 as a guide. The HP-41 Function Table (page 219) lists [XEQ] α in row 1, column 14, meaning that the hexadecimal value is 1E and the decimal value is 30. The remaining values we need are the decimal values for each character in "PLOTBC". The bit pattern to place in the ALPHA register is shown below. The checksum is omitted because it is inserted later by [BCCKSM].†

*The ALPHA register always contains 24 bytes of data. New data enters the ALPHA register from the right. [BC] (and the plotter option of the [BCO] function—described later in this section) ignores all null bytes to the left of the first non-null byte. Such null bytes do not appear when the ALPHA register is displayed. Each null byte to the right of the leftmost non-null byte appears as a - (overbar character) when you display the ALPHA register. If all bytes in the ALPHA register are nulls, [BC] generates a row of the paper keyboard bar code for zero.

†To print the bar code from this example on the HP 82162A Thermal Printer, ignore the pen movement instructions and replace the [BC] function with the following keystrokes: [CHS] [BCO].

Type	XEQ α	P	L	O	T	B	C

Selects pen 1.

Positions pen for new row.

Stores 64 in R_{01} for type indicator byte.Stores 30 in R_{02} for **XEQ** α function byte.Stores Alpha character values in R_{03} through R_{08} .Generates bit pattern in ALPHA from contents of R_{01} through R_{08} .

Displays bit pattern without checksum.

Generates eight-bit checksum as leftmost byte and moves all other bytes one place to the right.

Displays bit pattern with checksum. Notice that the checksum byte has been inserted.

Plots direct execution bar code for **XEQ** **PLOTBC**.

Returns pen to stall.

(If you are continuing to the next example, leave the current page in your plotter.)

With the PLOTBC program loaded into program memory and the HP-41 switched out of Program mode, scan the row you just plotted—the program should begin running.

Plotting Alternative (Non HP-41) Bar Code

When plotting alternative bar code types, it may be desirable to use different directional bits than those normally obtained with **BC**. The plotter option of the **BCO** function allows you to plot bar code using bit patterns that vary widely in their geometry and interpretation.

BCO
 (Plotter Option)

Z **number of bits**
 (leftmost byte)

Y **number of bits**
 (rightmost byte)

X **bb**

ALPHA **bit pattern**

The plotter option of the `BCO` (*bar code options*) function operates the same as `BC` except that:

- HP-41 directional bars are not automatically added to the row.
- You can specify how many rightmost bits from the first and last bytes to plot.
- Allows you to interpret bit patterns in alternative ways, depending upon the current bar code type. (Refer to the discussion of the `BCSIZE` function on page 111.)

Note: The *printer option* of the `BCO` function allows you to print HP-41 bar code on the HP 82162A Thermal Printer. (Refer to page 133 for more information.)

Thus, `BCO` allows you to determine your own leading and trailing bits for a plotted bar code row. This feature is most useful when you are designing non HP-41 bar code. Using `BCO` you can plot bar code rows having up to 192 bars (24 bytes).

Procedure. To use `BCO` (plotter option):

1. For a row containing **bb** bytes (not counting the directional bits) store in successive registers the decimal values for those bytes. (We will call these registers R_{iii} through R_{fff} .)
2. Determine the extra bits you need at the *beginning* (left end) of a bar code row containing the **bb** bytes.
3. Determine the decimal value of those bits.
4. Repeat steps 2 and 3 for the extra bits you need at the right end of the same row.
5. Store in R_{iii-1} (but not R_{00}) the decimal value of the byte you designed to contain the extra leading bits, and store in R_{fff+1} the decimal value of the byte you designed to contain the extra trailing bits.
6. Place in the X-register a number having the form **hhh.ggg**, where **hhh** = $iii - 1$ and **ggg** = $fff + 1$.
7. Execute `BCREGX` to place the bit pattern in the ALPHA register.
8. Enter in the Z- and Y-registers the number of rightmost bits you want plotted from the bytes in R_{iii-1} and R_{fff+1} , then enter in the X-register the total number of bytes contained in R_{iii-1} through R_{fff+1} ($f - i + 3$ bytes), and execute `BCO`.

(For bar code that has no leading or trailing bits you should enter 0 in both the Y- and Z-registers and the number of bytes in R_{iii} through R_{fff} ($f - i + 1$) in the X-register.)

Example: Plot a row of bar code containing the bit pattern for "ABCD." Instead of plotting the standard HP-41 directional bits use `BCO` to plot the row with 101 as alternative leading directional bits and 11 as alternative trailing directional bits. To determine the values to load into your HP-41:

	Leading Extra Bits	A	B	C	D	Trailing Extra Bits
Binary:	(00000)101	01000001	01000010	01000011	01000100	(000000)11
Hexadecimal:	0 5	4 1	4 2	4 3	4 4	0 3
Decimal:	5	65	66	67	68	3

As indicated in the above chart, the three rightmost bits in the first byte and the two rightmost bits in the last byte are the only parts of those two bytes that should be plotted in the desired row. *Even though this is type "0" bar code, it cannot be read by the wand because it does not have the standard HP-41 directional bits.*

Keystrokes	Display	
1 PEN	1.0000	Selects pen 1.
5 ENTER 55 MOVE	55.0000	Positions pen for new row.
5 STO 01	5.0000	Stores in R ₀₁ the byte containing the desired leading bits.
65 STO 02	65.0000	Stores in R ₀₂ through R ₀₅ the bytes containing the Alpha character values for "ABCD".
66 STO 03	66.0000	
67 STO 04	67.0000	
68 STO 05	68.0000	
3 STO 06	3.0000	Stores in R ₀₆ the byte containing the desired trailing bits.
6 BCREGX	6.0000	Generates bit pattern in ALPHA from contents of R ₀₁ through R ₀₆ .
3 ENTER	3.0000	Specifies that three bits of leftmost byte should be plotted.
2 ENTER	2.0000	Specifies that two bits of rightmost byte should be plotted.
6 BCO	6.0000	Plots bar code for bit pattern in ALPHA.
0 PEN	0.0000	Returns pen to stall.

(If you are continuing on to the next example, leave the current page in your plotter.)

The bit pattern in the row you just plotted should match the pattern in the following row.

General Operating Procedure. Using the same general procedure described earlier in this section, you can generate any type of bar code. To do this you (1) store the decimal equivalent of each byte into successive storage registers, (2) use **BCREGX** to generate the appropriate bit pattern in the ALPHA register, (3) calculate the checksum of the bit pattern using **BCCKSM**, and (4) execute **BC** to plot rows having standard HP-41 directional bits, or execute the plotter option of the **BCO** function to plot different bar codes having either directional bits that you specify or no directional bits at all.*

The bar code type used thus far in this manual (and all HP-41 bar code) is type "0" bar code which consists of uniformly spaced wide and narrow bars (as "0"s and "1"s). When you want to generate another type of bar code, reset the plotter module to that type by executing **BCSIZE** before you begin plotting the bar code rows (refer to Changing the Bar Code Size and Type, page 111).

For some types of bar code you may also want to adjust the bar code size parameters to achieve the correct width ratio between bars and spaces. In some cases this involves a process of experimenting with various parameters.

Type 1. Type 1, or *alternating*, bar code uses both spaces and bars in the bit pattern. The components of this type are:

- Wide bars or wide spaces equal "1".
- Narrow bars or narrow spaces equal "0".

*You can use the printer option of **BCO** to generate nonstandard HP-41 bar code on the HP 82162A Thermal Printer. If nonstandard bar code has the standard HP-41 directional bits, it can be read by the wand using **WNBSCN** or **WNBST**.

All bit patterns begin with a bar which may be wide ("1") or narrow ("0") and use alternating bars and spaces to show the bit pattern. That is, a bit can be either a bar or a space.

Type 2. Type 2, or *proportional*, bar code represents each bit as a bar and a space. Thus, a "1" could be represented as a 2-unit bar and a 1-unit space, and a "0" represented as a 1-unit bar and a 2-unit space—each bit is 3 units wide.

Type 3. This type is a utility bar code provided to allow advanced users to create any type of bar code. The components of this type are:

- Narrow bars equal "1".
- Narrow spaces equal "0".

It is possible to use this type designator to produce any of the preceding bar code types, as well as bar code that resembles Universal Product Code.

Example: The previous example plots a row of type 0 bar code. Now plot the same row in types 1, 2, and 3. The following table shows the **BCSIZE** parameters to use if your pen's actual width is 10 APUs. (If you are unsure of your pen's width, execute the PWIDTH program and use the indicated pen width instead of the 10 APU pen width shown in the table. However, do not alter any of the other values specified by the table.)

BCSIZE Parameters

Type	Y-Register				X-Register		
	<i>nn</i>	<i>t</i>	<i>ww</i>	<i>ss</i>	<i>pp</i>	<i>hhh</i>	<i>aa</i>
1	15.	1	30	15	10.	350	30
2	15.	2	30	15	10.	350	30
3	12.	3	00	13	10.	999	

Before you begin, ensure that the bit pattern generated in the preceding example is in the ALPHA register.

Returns pen to stall and resets bar code parameter to default value.

Plotting Conditions and the Input/Output Buffer

Contents

Introduction	148
The 26-Register I/O Buffer (PRCL)	148
Default Plotting Conditions	150

Introduction

In order to perform plotter scaling in your HP-41, as well as several other plotting functions, a variety of scale factors and other data are automatically maintained in HP-41 memory. To protect these values from being inadvertently cleared or altered by normal operations, they are placed in a buffer composed of 26 HP-41 storage registers. (Refer to Minimum Memory Requirements, page 11, and Initializing and Clearing the I/O Buffer, page 68.) You can inspect these registers using the **PRCL** function described on the next page. However, since direct inspection of the I/O buffer contents is not essential for most users and applications, you may want to skip the remainder of this section unless your applications require you to know specific I/O buffer information.

The 26-Register I/O Buffer

The following diagram describes the contents of the I/O buffer. (Certain operations, such as bar code functions, use these registers differently than shown below.) Because coordinate information is converted into APUs ("absolute plotter units" used by plotters) before it is sent to a plotter, the I/O buffer stores information in terms of APUs. Pen positions expressed in APUs are restricted to the range -32768 to $+32767$ to be compatible with the numerical range of plotters.

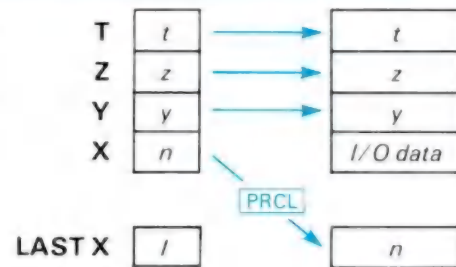

BR ₀₀	Status Information	
BR ₀₁	P1 _x	} Lower left-hand and upper right-hand corners of graphic limits in APUs.
BR ₀₂	P2 _x	
BR ₀₃	P1 _y	
BR ₀₄	P2 _y	
BR ₀₅	x ₁	} Lower left-hand and upper right-hand corners of plot bounds in APUs.
BR ₀₆	x ₂	
BR ₀₇	y ₁	
BR ₀₈	y ₂	
BR ₀₉	Last x	} Intended pen position in APUs after most recent plotting or LABEL command.
BR ₁₀	Last y	
BR ₁₁	Misc x	} Miscellaneous storage.
BR ₁₂	Misc y	
BR ₁₃	Last x'	} Actual pen position in APUs after most recent plotting or LABEL command.
BR ₁₄	Last y'	

BR ₁₅	Misc x'	} Miscellaneous storage.
BR ₁₆	Misc y'	
BR ₁₇	Factor 1 x	} GU Scaling Factors (GUs \rightarrow APUs).
BR ₁₈	Factor 2 x	
BR ₁₉	Factor 1 y	
BR ₂₀	Factor 2 y	
BR ₂₁	Factor 1 x'	} UU Scaling Factors (UUs \rightarrow APUs).
BR ₂₂	Factor 2 x'	
BR ₂₃	Factor 1 y'	
BR ₂₄	Factor 2 y'	
BR ₂₅	BCSIZE Parameters	\rightarrow (Recalled as alpha string.)

PRCL**X** register number

The **PRCL** (recall I/O parameter) function recalls to the X-register the contents of the I/O buffer register specified by the absolute value of the number in the X-register. The I/O register number must be from 0 through 25. The function ignores fractional portions of such numbers.

The values stored in buffer registers 01 through 25 are described in the illustration above.

If you specify a register number of 0, **PRCL** returns a number representing several values stored in BR₀₀ and encoded as

$$m . n_1 n_2 n_3 n_4 n_5 n_6 n_7$$

where

m : **LORG** value. (Refer to page 94.)

n_1 : **PDIR** angle θ indicator. (Refer to page 86.)

n_1	Conditions		Quadrant
0	$\cos \theta \geq 0$	$\sin \theta \geq 0$	I
1	$\cos \theta < 0$	$\sin \theta \geq 0$	II
2	$\cos \theta \geq 0$	$\sin \theta < 0$	IV
3	$\cos \theta < 0$	$\sin \theta < 0$	III

$n_2 - n_5$: Cosine of **PDIR** angle θ in **x.xxx** format (without sign).

n_6 : **RPLOT** indicator. (Refer to page 82.)

n_6	Condition
0	RPLOT not last function
2	RPLOT was last function

n_7 : Plotting status.

n_7	Plot Mode	Pen Status	Last Point Specified
0	GU	Up	In Bounds
1	GU	Up	Out of Bounds
2	GU	Down	In Bounds
3	GU	Down	Out of Bounds
4	UU	Up	In Bounds
5	UU	Up	Out of Bounds
6	UU	Down	In Bounds
7	UU	Down	Out of Bounds

Example of `PRCL` Execution. Determine the default plotting conditions that the plotter module sets in BR_{00} .

Keystrokes	Display	
<code>PINIT</code>		Initializes plotting system.
0 <code>PRCL</code>	1.0100	Displays contents of I/O buffer status register (BR_{00}).
■ <code>FIX</code> 7	1.0100004	Sets <code>FIX</code> 7 display mode to show all digits in the buffer register.
■ <code>FIX</code> 4	1.0100	Restores <code>FIX</code> 4 display.

The indicated default conditions for the HP 7470A Plotter are

- `LOG` value: 1.
- `PDIR` quadrant: I.
- Cosine `PDIR` angle: 1.000.
- `RPLT` not last function.
- UU mode.
- Pen up.
- Last point in bounds.

Default Plotting Conditions

Executing `PINIT` or `LIMIT` sets the following default conditions:

- Reads the P1 and P2 coordinates from the plotter (except that `LIMIT` first sets P1 and P2 from data in the stack) and uses the corresponding points as the diagonal end points of the graphic limits.
- Determines the GU scale factors $1x$, $2x$, $1y$, $2y$ to generate a GU scale. (Refer to `RATIO` on page 71.)
- Sets the UU scale factors $1x'$, $2x'$, $1y'$, and $2y'$ equal to the GU scale factors described above and sets the plotter to UU mode.
- Selects pen 1.
- Selects line type 1.
- Selects label origin 1.

- Sets character space height to 3 GUs.
- Sets label direction as left-to-right.
- Sets angular rotation of axes for incremental and relative plotting to zero.
- Sets the tic length to the plotter's default value.
- Clears any error conditions.

Executing `PINIT` when an I/O buffer does not already exist sets default `BCSIZE` parameters for bar code geometry—otherwise, `BCSIZE` parameters remain unchanged.

APPENDICES

Error Messages

This appendix contains a list of messages and errors that are related to plotter module *functions*. For each error message listed below, the possible causes are listed according to the plotter functions that generate that message.

For error conditions that occur during execution of the user-language plotting routines (**NEWPLOT**, **REPLOT**, **PLINIT**, **PLTUXY**, **PLANOT**), the bar-code subroutines, PLOTBC, or other programs, set the HP-41 to Program mode. The function in the displayed program line is the one that caused the error. If it's a plotter function, refer to the list below. Otherwise, refer to the owner's manual for the HP-41 extension that provides that function.

Display	Functions	Meaning
ALPHA DATA	-all-	Alpha characters are in a register where a number is required—either a stack register or a data storage register.
DATA ERROR	BCCKSM BCO BCP BCREGX BCSIZE RATIO SCALE	$x = 0$. $x \geq 25$ or $x \leq -17$. $x \geq 1000$. For any specified register, $ contents \geq 256$. $nn \neq 0$ and $nn \leq pp$, $ww \neq 0$ and $ww \leq pp$, $pp + ss > 97$, $pp + aa > 97$, nn not specified and $pp > 66$, ww not specified and $pp > 38$, $0 < nn < pp $, or $0 < ww < pp $, where $x = pp.hhhaa$ and $y = nn.twwss$. y-minimum = y-maximum for the graphic limits. x-minimum = x-maximum, or y-minimum = y-maximum.
NO PLOTTER	-all-	A standard plotter (accessory types 96 through 111) is not in the interface loop. (Occurs in Auto mode only—flag 32 clear.)
NONEXISTENT	BCREGX BCO BCP BCXS PLREGX PRCL BCP	$ x \geq 1000$. For $x < 0$, an HP-IL module is not connected, its Print Function Switch is not set to ENABLE, or an HP 82162A Thermal Printer is not connected (or is not the primary device in Manual interface mode—flag 32 set). Function specifies a nonexistent program. $ y \geq 1000$. Function specifies a nonexistent data register. Function specifies a register numbered higher than 25. Specified program had not been packed.
PACKING TRY AGAIN		

Display	Functions	Meaning
PL:NO HPIL	-all-	An HP 82160A HP-IL module is not plugged into the HP-41.
PL:NO ROOM	PINIT	There are less than 26 memory registers available to build the I/O buffer.
PL:PLS PINIT	-all-	The I/O buffer does not exist.
PL:RANGE ERR	LIMIT	A plotting area larger than the plotter's mechanical limits has been specified.
	LXAXIS	Function specifies a tic spacing of zero, $x\text{-maximum} \leq x\text{-minimum}$ or $y\text{-maximum} \leq y\text{-minimum}$. A specified value converts to a point beyond the physical limits of the plotter.
	LYAXIS	
	XAXIS	
	XAXISO	
	YAXIS	
	YAXISO	
ROM	BCP	Specified program is in ROM (read-only memory) in a plug-in module. (Use COPY first.)
TRANSMIT ERR	-all-	Interface loop is not connected or a device is turned off. In Manual interface mode, the primary device may not be able to perform the operation; select the proper device.

Module Care

CAUTION

Always turn off the HP-41 before connecting or disconnecting any module or peripheral. Failure to do so could result in damage to the HP-41 or disruption of the system's operation.

- Keep the contact area of the module free of obstructions. Should the contacts become dirty, carefully brush or blow the dirt out of the contact area. Do not use any liquid to clean the contacts.
- Store the module in a clean, dry place.
- Always turn off the computer before installing or removing any module or peripherals.
- Observe the following temperature specifications:
 - Operating: 0°C to 45°C (32°F to 113°F).
 - Storage: -40°C to 75°C (-40°F to 167°F).

Limited One-Year Warranty

What We Will Do

The HP 82184A Plotter Module is warranted by Hewlett-Packard against defects in materials and workmanship affecting electronic and mechanical performance, but not software content, for one year from the date of original purchase. If you sell your unit or give it as a gift, the warranty is automatically transferred to the new owner and remains in effect for the original one-year period. During the warranty period, we will repair or, at our option, replace at no charge a product that proves to be defective, provided you return the product, shipping prepaid, to a Hewlett-Packard service center.

What Is Not Covered

This warranty does not apply if the product has been damaged by accident or misuse or as the result of service or modification by other than an authorized Hewlett-Packard service center.

No other express warranty is given. The repair or replacement of a product is your exclusive remedy. **ANY OTHER IMPLIED WARRANTY OF MERCHANTABILITY OR FITNESS IS LIMITED TO THE ONE-YEAR DURATION OF THIS WRITTEN WARRANTY.** Some states, provinces, or countries do not allow limitations on how long an implied warranty lasts, so the above limitation may not apply to you. **IN NO EVENT SHALL HEWLETT-PACKARD COMPANY BE LIABLE FOR CONSEQUENTIAL DAMAGES.** Some states, provinces, or countries do not allow the exclusion or limitation of incidental or consequential damages, so the above limitation or exclusion may not apply to you.

This warranty gives you specific legal rights, and you may also have other rights which vary from state to state, province to province, or country to country.

Warranty for Consumer Transactions in the United Kingdom

This warranty shall not apply to consumer transactions and shall not affect the statutory rights of a consumer. In relation to such transactions, the rights and obligations of Seller and Buyer shall be determined by statute.

Obligation to Make Changes

Products are sold on the basis of specifications applicable at the time of manufacture. Hewlett-Packard shall have no obligation to modify or update products once sold.

Warranty Information

If you have any questions concerning this warranty or service, please contact an authorized Hewlett-Packard dealer or a Hewlett-Packard sales and service office. Should you be unable to contact them, please contact:

- In the United States:

Hewlett-Packard

Corvallis Division

1000 N.E. Circle Blvd.

Corvallis, OR 97330

Telephone: (503) 758-1010

Toll-Free Number: (800) 547-3400 (except in Oregon, Hawaii, and Alaska)

- In Europe:

Hewlett-Packard S.A.

7, rue du Bois-du-Lan

P.O. Box

CH-1217 Meyrin 2

Geneva

Switzerland

Telephone: (022) 83 81 11

Note: Do not send units to this address for repair.

- In other countries:

Hewlett-Packard Intercontinental

3495 Deer Creek Rd.

Palo Alto, California 94304

U.S.A.

Telephone: (415) 857-1501

Note: Do not send units to this address for repair.

Service

Obtaining Repair Service in the United States

The Hewlett-Packard United States Service Center for handheld and portable computer products is located in Corvallis, Oregon:

Hewlett-Packard Company
Corvallis Division Service Department
P.O. Box 999/1000 N.E. Circle Blvd.
Corvallis, Oregon 97330, U.S.A.
Telephone: (503) 757-2000

Obtaining Repair Service in Europe

Service centers are maintained at the following locations. For countries not listed, contact the dealer where you purchased your unit.

AUSTRIA

International Service Information

Not all Hewlett-Packard service centers offer service for all models of HP products. However, if you bought your product from an authorized Hewlett-Packard dealer, you can be sure that service is available in the country where you bought it.

If you happen to be outside of the country where you bought your module, you can contact the local Hewlett-Packard service center to see if service is available for it. If service is unavailable, please ship the module to the address listed above under Obtaining Repair Service in the United States. A list of service centers for other countries can be obtained by writing to that address.

All shipping, reimportation arrangements, and customs costs are your responsibility.

Technical Assistance

The keystroke procedures and program material in this manual are supplied with the assumption that the user has a working knowledge of the concepts and terminology used. Hewlett-Packard's technical support is limited to explanation of operating procedures used in the manual and verification of answers given in the examples. If you have technical problems involving this manual, consult your HP-41 owner's manual. Should you need further assistance, write to:

Hewlett-Packard
Corvallis Division Customer Support
1000 N.E. Circle Blvd.
Corvallis, OR 97330

Dealer and Product Information

For U.S.A. dealer locations, product information, and prices, please call (800) 547-3400. In Oregon, Alaska, or Hawaii, call (503) 758-1010.

Plotter supplies are available from many authorized Hewlett-Packard dealers and from Hewlett-Packard sales offices. In the U.S.A. you can also order plotter supplies through the *Personal Computer Supplies and Accessories* catalog (part number 5953-2010) or the *Computer Users' Catalog* (part number 5953-2450), either of which you can receive without charge by writing to:

Hewlett-Packard
Computer Supplies Operation
P.O. Box 60008
Sunnyvale, California 94088

```

Gets PLTPRM type. If
 $x = 0$ executes user
routine. If $x = 1$ or 3,
performs point plotting. If
 $x = 2$, performs autoscale.

Initializes plotting area
regardless of x/y ratio.

Sets user scale.

Plot Routine. If PLTPRM
is Alpha data, goes to
LBL 00. Otherwise gets
desired pen and line type.

Sets x_0 in R_{10} and
changes number of
increments to increment
value, if needed.

If plotting buffer, stores
point count in R_{11} .
Otherwise sets to 1,000
points.

Clears "done" flag.

Go to LBL 04 if not plotting buffer. Otherwise, get buffer type and go to that buffer.

Plot type 0 buffer.

If type 1 buffer, get x_i from XINC and y_i from buffer.

If type 2 buffer, get x_i and y_i from buffer.

Non-buffered plotting. Get x_i from XINC and y_i from NAME.

PLTPRM end of loop.

Clean up. If buffer was just built, store pointer and buffer type in R_{08} and insert zero for buffer-building parameters.

If autoscale was just done, resets PLTPRM to 11, resets XAXAT and YAXAT, sets scale just identified, and returns.

Returns pen, presents plot, and ends.

If XINC is alpha, gets x_i from user routine. If R_{05} is numeric, $x_i = x_{i-1} + \text{XINC}$.

Test PLTPRM parameter. If numeric, go to LBL 00. If PLTPRM is alpha, go to routine specified by label in R_{02} (PLTPRM).

If not filling a buffer, go to LBL 04. Otherwise go to LBL number corresponding to buffer type.

Stores x and y for type 0
or type 2 buffer.

Stores y for type 1 buffer.

Plots point. Plots
character if desired (and
printer code is available).

The BAR Subroutine

BAR generates histograms when used in conjunction with the PLTPRM parameter in the Utility Plotting Program described in section 2. BAR increases the number of reserved registers in the **NEWPLOT** data base to 13 (R_{00} through R_{12}). Register 12 is used to store a parameter that you must enter in the form of *pff.ww* where

p determines the pen number.

ff determines the fill density by designating the number of lines used to shade the bar.

ww represents a percentage of the x-axis used to determine the width of the bars.

BAR plots bars only within the plotting limits.

Bar code for the following listing is on pages 195 and 196.

Tests y against YMAX
AND YMIN and replaces
 y if out of bounds. Stores y
in Z. Sets tic length to
100% and selects specified
pen.

The TITLES Subroutine

TITLES is an independent subroutine that initially prompts you for a plot title using a **PTITL?** prompt. Entering a number terminates interactive prompting. TITLES interprets a numeric input as a pointer to 12 consecutive registers containing a plot title in the first four registers, an x-units title in the next four registers, and a y-units title in the last four registers. TITLES accumulates only Alpha data during the scan of these registers (that is, if you want to omit specific titles, store numeric data in the corresponding registers).

An Alpha response is limited to 24 characters and appears centered above the plot using pen 2 and **CSIZE** 5. A **R/S** with no data entry suppresses the main title. Subsequent prompts of **XTITL?** and **YTITL?** may be answered with Alpha data or no data entry. Conditions for these labels are **PEN** 1 and **CSIZE** 3. After printing the label, the pen moves to (GU) point (0,0). The pen is then put away and the plotter is set to UUs.

TITLES assumes your plotter is already initialized and scaled.

Bar code for the following listing is on pages 206 and 207.

If numeric register pointer is entered, gets data from registers.	<pre> 01*LBL "TITLES" 02 CF 22 03 CF 23 04 "PTITL?" 05 AON 06 PROMPT 07 AOFF 08 FS?C 22 09 GTO 05 10 CLA 11 .1 12 / 13 * 14 .003 15 + 16 STO 10 17 XEQ 00 18 XEQ 02 19 .003 20 ST+ 10 21 XEQ 00 22 XEQ 03 23 .003 24 ST+ 10 25 XEQ 00 26 XEQ 04 27 RTN 28*LBL 05 29 FS?C 23 30 XEQ 02 31 "XTITL?" 32 AON 33 PROMPT 34 AOFF 35 FS?C 23 36 XEQ 03 37 "YTITL?" 38 AON 39 PROMPT 40 AOFF 41 FS?C 23 42 XEQ 04 43 GTO 06 44*LBL 06 45 RCL IND 10 46 SIGN 47 X=0? 48 ARCL IND 10 </pre>	Regardless of P1, P2 setting, positions pen and labels chart title.	<pre> 49 ISG 10 50 GTO 00 51 RTN 52*LBL 02 53 4 54 PRCL 55 24 56 PRCL 57 - 58 23 59 PRCL 60 / 61 RCL 01 62 RCL 00 63 + 64 2 65 PEN 66 / 67 MOVE 68 6 69 ENTER↑ 70 5 71 GTO 07 72*LBL 03 73 3 74 PRCL 75 24 76 PRCL 77 - 78 23 79 PRCL 80 / 81 RCL 01 82 RCL 00 83 + 84 2 85 / 86 MOVE 87 1 88 PEN 89 4 90 ENTER↑ 91 3 92*LBL 07 93 CSIZE 94 RDH 95 LONG </pre>

Pen Width Calibration (Page 110)

Sets display for labels,
initializes plotter, sets
label direction to 90°, sets
x-coordinate and counter
in R₀₁, sets pen width
parameter in R₀₂. Clears
ALPHA, and sets
y-coordinate and counter
in R₀₀.

Gets y and x and moves to
that point. Places current
pen width in ALPHA for
label. Sets narrow bars to
26 plotter units and space
to 4 plotter units. Sets pen
width to current R₀₂ value
and labels this pen size.
Plots 1 null byte using
BCO. Increments pen
parameter and value in Y,
then goes to R₀₂, or
increments value in X and
goes to R₀₁, or returns pen
and halts.

Printing a Program on the HP 82162A Thermal Printer (Page 136)

The PRBC program prompts you for a program name and prints the program in bar code form on the HP 82162A Thermal Printer. PRBC assumes that the HP 82162A printer is connected to the system (*and that an HP 82143A Printer is not plugged into the HP-41*). It is unnecessary to have a plotter in the interface loop when you execute PRBC.

Set flag 25 (Error Ignore Flag—refer to your HP-41 owner's manual) so that **PINIT** does not cause a **NO PLOTTER** error condition.*

Clears flag 29 and sets **FIX** 0 display mode so that row label has no decimal part.

```

01 *LBL "PRBC"
02 SF 25
03 PINIT

```

```

04 CF 29
05 FIX 0

```

Gets program name. If no name is entered (or if flag 23 is clear), executes **RTN**.

Starts at row 1 and makes each row nine bytes long.

Prints row label.

```

06 CF 23
07 "NAME?"
08 RDN
09 PROMPT

```

```

15 *LBL 01
16 "ROW: "
17 ARCL X
18 PRA

```

*BCP requires that the 26-register I/O buffer be present. **PINIT** creates this buffer and also ensures that the HP-IL module is plugged in and that a plotter is in the loop. **PINIT** produces an error message if there is no plotter or if the HP-IL module is not plugged into the HP-41. However, **PINIT** creates the buffer *before* it checks for these conditions. To print HP-41 bar code on the HP 82162A Thermal Printer when a plotter is *not* plugged into the loop, set flag 25 *before* executing **PINIT**.

Gets bit pattern of current row,	19 BCP
Gets number of bytes from T.	20 RT
Value in X must be negative.	21 CHS
Prints row.	22 BCO
Restores stack order.	23 RDN

If finished with program (next row is zero), halts execution. Otherwise, goes to **LBL** 01 and prints next row.

{	24 X=0?
	25 GTO 01
	26 END

The PLPLOT/PLPLOT Subroutine

PLPLOT/PLPLOT allows you to execute a function plot on the HP 82162A Thermal Printer, then translate the data base and generate the function plot on an HP 7470A Plotter.

Rearranges data base and goes to **PLOT?** prompt.
Lets user adjust data base.

Character Codes	212

Introduction

This appendix provides you with XROM information that is useful in some programming operations. Also included, for users familiar with plotters operated by desktop or larger computers, is a comparative listing of plotting function used in the plotter module, the HP-GL (Hewlett-Packard Graphic's Language), and the Hewlett-Packard Series 80 computers.

Programmable Function XROM Numbers

The HP 82184A Plotter Module's programmable functions can be entered in a program whenever the module is plugged into the HP-41, regardless of whether or not a plotter is also plugged in. While the module is plugged in, program lines containing plotter module functions are displayed and printed using the standard function names. If you later disconnect the module, these program lines are displayed and printed as XROM functions—with two identification numbers. These numbers indicate that the function belongs to a plug-in accessory. The first number identifies the accessory. (XROM accessory numbers 17 and 18 correspond to the plotter module.) The second number identifies the function for that accessory. When you remove the plotter module, its functions have the following XROM numbers.

Function	XROM Number	Function	XROM Number	Function	XROM Number
CLIPUU	XROM 17,01	MOVE	XROM 17,21	PDIR	XROM 18,02
CSIZE	XROM 17,02	PEN	XROM 17,22	PRCL	XROM 18,03
CSIZEO	XROM 17,03	PENDN	XROM 17,23	NEWPLOT	XROM 18,04
DGTIZE	XROM 17,04	PENUP	XROM 17,24	RELOT	XROM 18,05
DRAW	XROM 17,05	PINIT	XROM 17,25	PLINIT	XROM 18,06
FRAME	XROM 17,06	PLOT	XROM 17,26	PLTUXY	XROM 18,07
GCLEAR	XROM 17,07	PLREGX	XROM 17,27	PLANOT	XROM 18,08
IDRAW	XROM 17,08	RATIO	XROM 17,28	Y?	XROM 18,09
IMOVE	XROM 17,09	RPLLOT	XROM 17,29	X?	XROM 18,10
IPLOT	XROM 17,10	SCALE	XROM 17,30	BC	XROM 18,11
LABEL	XROM 17,11	SETGU	XROM 17,31	BCA	XROM 18,12
LDIR	XROM 17,12	SETUU	XROM 17,32	BCAA	XROM 18,13
LIMIT	XROM 17,13	TICLEN	XROM 17,33	BCCKSM	XROM 18,14
LOCATD	XROM 17,14	UNCLIP	XROM 17,34	BCO	XROM 18,15
LOCATE	XROM 17,15	WHERE	XROM 17,35	BCP	XROM 18,16
LORG	XROM 17,16	XAXIS	XROM 17,36	BCREGX	XROM 18,17
LTYPE	XROM 17,17	XAXISO	XROM 17,37	BCSIZE	XROM 18,18
LTYPEO	XROM 17,18	YAXIS	XROM 17,38	BCX	XROM 18,19
LXAXIS	XROM 17,19	YAXISO	XROM 17,39	BCXS	XROM 18,20
LYAXIS	XROM 17,20	PCLBUF	XROM 18,01		

If you use **XEQ** to enter a plotter module function into a program line for example, by setting the HP-41 to Program mode and pressing **XEQ** **ALPHA** **MOVE** **ALPHA** while the plotter module is not connected, the function is recorded, displayed, and printed as **XEQ^T** followed by the function name. Lines of this form slow program execution because the HP-41 searches for a matching Alpha label or function name—first in program memory, then in each module that is currently plugged in.

HP-GL Commands and Series 80 Counterparts

The following listings are provided for users who want to know the HP-GL (Hewlett-Packard Graphics Language) commands used internally in the HP 82184A Plotter Module's functions and/or the plotter module's function counterparts in the Hewlett-Packard Series 80 computers.

Plotter Module Function	HP-GL Functions Used	Series 80 Counterparts	Series 80/Plotter Module Functionality

Introduction

The charts in this appendix provide you with a guide to constructing headers and determining function codes for the various types of HP-41 bar code described in section 7, Bar Code. This information is provided to aid advanced users whose applications require that they design the byte structure in individual bar code rows.

Specification Charts for HP-41 Bar Code

Alpha Data Bar Code

A	B	C	D
Header			Alpha Data
A	8-bit Checksum (End-around Carry)		
B	4-bit Type Indicator (Set to 7 or 8), where 7 = Alpha Replace 8 = Alpha Append		
C	4-bit Number of ASCII Characters in String		
<hr/>			
	16-bit (2-Byte) Header		
D	Up to 14 Alpha Characters		

Numeric Data and Sequenced Data Bar Code

A string of valid binary-coded digits in part C of numeric data bar code or part D of numeric sequenced data bar code consists of:

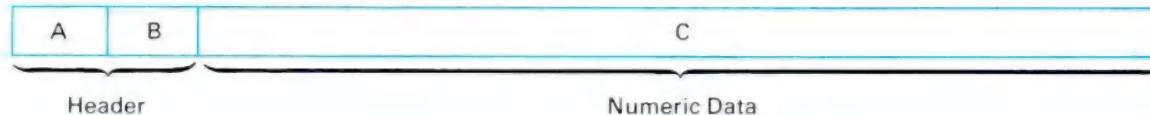

- One numeric digit (0 through 9) for each of one to ten mantissa digits, and, if needed, up to two exponent digits.
- When needed, a null (filler) digit, which is used as the first digit in the data string. (Refer to following table.)

- When needed, data specifying a decimal point, "+" sign, "-" sign, and "E" exponent symbol. (Refer to following table.)

Numeric Data Functions

Digit	Code
0	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000
9	1001
Null (hex. "A")	1010
"." (hex. "B")	1011
"+" (hex. "C")	1100
"-" (hex. "D")	1101
"E" (hex. "E")	1110
Illegal (hex. "F")	1111

Numeric Data Bar Code.

- A 8-bit Checksum (End-around Carry)
- B 4-bit Type Indicator (Set to 6)
- 12-bit Header (1½ Bytes)
- C Up to 10 mantissa digits and 2 exponent digits, plus (when needed) filler digits, the mantissa sign, the exponent sign, and the decimal point.

The row must be a minimum of three bytes long. If C contains only one digit, insert a pair of filler digits at the beginning of C. If C contains an even number of digits, insert one filler digit at the beginning of C. For example:

Number (Decimal)	Bit Pattern (Hexadecimal)			
	A	B	C	
	Checksum	Type	Filler(s)	Data
2	1 0	6	A A	2
24	8 E	6	A	2 4
2.4	1 8	6	none	2 B 4
2.4E4	F C	6	none	2 B 4 E 4
2.4E-4	6 9	6	A	2 B 4 E D 4

Sequenced Data Bar Code. This type of bar code is used with revision F and any subsequent revisions of the HP 82153A Wand. (Refer to the note on page 129.)

A	B	C	D
Header			Data

- A 8-bit Checksum (End-around Carry)
- B 4-bit Type Indicator (Set to 9 or 10), where
9 = Numeric Data
10 = Alpha Replace
- C 12-bit Sequence Number
- 24-bit (3-Byte) Header
- D Up to 10 mantissa digits and 2 exponent digits, plus (when needed) a filler digit, the mantissa sign, the exponent sign, and the decimal point; or up to 13 ALPHA characters.

The row must be a minimum of four bytes long. If D contains an odd number of digits, insert one filler digit at the beginning of D. For example:

Number (Decimal)	Bit Pattern (Hexadecimal)				
	A	B	C	D	
	Checksum	Type	Seq. No.	Filler	Data
123.6 Seq. = 1	0 F	9	0 0 1	A	1 2 3 B 6
1.236E23 Seq. = 2	6 3	9	0 0 2	none	1 B 2 3 6 E 2 3
1.236E-23 Seq. = 3	3 2	9	0 0 3	A	1 B 2 3 6 E D 2 3

Program Bar Code

A	B	C	D	E	F
Header					Program Information

- A 8-bit Checksum (End-around Carry)
- B 4-bit Type Indicator (Set to 1 or 2), where
1 = Nonprivate
2 = Private
- C 4-bit Sequence Number (Mod 16)
- D 4-bit Number of Leading Broken Function Bytes
- E 4-bit Number of Trailing Broken Function Bytes
- 24-bits = 3-Byte Header
- F Up to 13 Bytes of Program Information

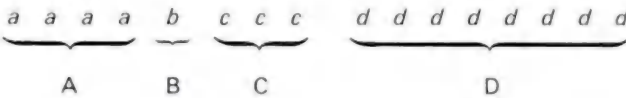

One-Byte Paper Keyboard Bar Code

	$\underbrace{a \ a \ a \ a}_A$	$\underbrace{b \ b \ b \ b}_B$
Function	Value of A	Value of B
0	0000	0000
1	1000	0001
⋮	⋮	⋮
9	1001	1001
	0101	1010
	1101	1011
	0011	1100
	1011	1101

Direct Execution Bar Code

A	B	C	D
Header			Complete Function Code
A	8-bit Checksum (End-around Carry)		
B	4-bit Type Indicator (Set to Four)		
C	4-bit Unused (Set to Zero)		
<hr/>			
	16-bits = 2-Byte Header		
D	Up to 12 Bytes for Function Code		

Two-Byte Paper Keyboard

- Programmable Functions. These functions are found in the following locations in the HP-41 Function Table on the following page.
 - Row 4, column 0, through Row 9, column 15
 - Row 10, columns 8 through 14
 - Row 12, columns 0, 14, and 15
 - Row 13, column 0
 - Row 14, column 0
 - A 4-bit Checksum (End-around Carry)
 - B 0
 - C 000
 - D 8-bit Function Code
(Such as ABS, Row 6 Column 1 = 01100001)

2. Alpha Characters (Keys)

- A 4-bit Checksum (End-around Carry)
- B 0
- C 001
- D 8-bit ASCII with Most Significant 4 Bits Doubled
(For example the ASCII for "A" is 01000001. With most significant nybble doubled, the bar code value for the character A becomes 10000001.)

3. Indirect

- A 10 (1010)
- B 0
- C 2 (010)
- D 128 (10000000)

4. Non-Programmables

- A 4-bit Checksum (End-around Carry)
- B 0
- C 4 (100)

Function	Value	Function	Value
D CAT	0	SST	8
GTOL	1	STAYON	9
DEL	2	PACK	10
COPY	3	DELETE	11
CLP	4	ALPHA	12
R/S	5	PRGM	13
SIZE	6	USER	14
BST	7	ASN	15

5. XROM

- A 4-bit Checksum (End-around Carry)
- B 1
- C *fff*
- D *gg h h h h h h*
 $fff gg = \text{ROM I.D. Number}$
 $h h h h h h = \text{ROM Function Number}$

For Example: **WNDSCN** has ROM I.D. = 27 and ROM Function = 5. Therefore *fffgg* = 11011, and *hhhhhh* = 000101.

Programmable Function Derivation

Position in HP-41 Function Table		Contents of:				
Row	Column	Function	Byte 3	Byte 4	Byte $N + 4$
1	13, 14	<div>GTO</div> , <div>XEQ</div> (Alpha)	(Row No. $\times 16$) + Column No.	1st ASCII Character		N th (Last) ASCII Character
4-8	0-15	Refer to HP-41 Function Table.		N/A		N/A
9	0-15			Numeric Value of Argument		N/A
10	0-7	XROM	(Refer to Two-Byte Paper Keyboard Chart.)			N/A
10	8-13	Refer to HP-41 Function Table	(Row No. $\times 16$) + Column No.	Numeric Value of Argument		N/A
10	14	<div>GTO</div> / <div>XEQ</div> ■ (IND)		Numeric Value of Argument (If GTO, msb = 0; if XEQ, msb = 1)		N/A
12	0-13	<div>LBL</div> , <div>END</div>	(Row No. $\times 16$) + 13 (LBL) or 0 (END)	1st ASCII Character		N th (Last) ASCII Character
12	14, 15	Refer to HP-41 Function Table.	(Row No. $\times 16$) + Column No.	Numeric Value of Argument		N/A
13, 14	0-15		(Row No. $\times 16$) + 0	Numeric Value of Argument		N/A

Nonprogrammable Bar Code

Non-programmable Function	Contents of: (N = The Number of ASCII Characters)					
	Byte 3	Byte Four	Byte Five	...	Byte N + 3	Byte N + 4
CATALOG	0	Catalog Number	N/A		N/A	N/A
GTO	1	Argument (right justified)			N/A	N/A
GTO	1	15	255		N/A	N/A
DEL	2	Argument (right justified)			N/A	N/A
COPY	3	1st ASCII Character	2nd ASCII Character		Nth ASCII Character	N/A
CLP *	4	1st ASCII Character	2nd ASCII Character		Nth ASCII Character	N/A
R/S	5	N/A	N/A		N/A	N/A
SIZE	6	Argument (right justified)			N/A	N/A
BST	7	N/A	N/A		N/A	N/A
SST	8	N/A	N/A		N/A	N/A
ON	9	N/A	N/A		N/A	N/A
PACK	10	N/A	N/A		N/A	N/A
DELETE	11	N/A	N/A		N/A	N/A
ASN	15	$A \times 16 + B^{\dagger}$	1st ASCII Character		N - 1 ASCII Character	Nth ASCII Character ($N < 7$)

* This three-byte bar code by itself will clear the program where the PC (program counter) is located. If there is an argument it is an Alpha string.

[†] $A = \text{ABS}(\text{keycode}) \text{ DIV } 10$, $B = \text{ABS}(\text{keycode}) \text{ MOD } 10$. If $\text{keycode} < 0$ then $A = [\text{ABS}(\text{keycode}) \text{ Div } 1048] \text{ MOD } 16$.

Function Index

General Plotting Functions:

CLIPUU	Specifies plot bounds in user units.	Page 74
CSIZE	Sets character space height.	Page 97
CSIZEO	Sets character space height, aspect ratio, and slant.	Page 97
DGTIZE	Identifies coordinates of current pen position.	Page 104
DRAW	Draws line to point (x,y).	Page 78
FRAME	Frames active plotting area.	Page 78
GCLEAR	Advances page on plotters that have a page feed mechanism.	Page 75
IDRAW	Draws line to a point x and y units from current point.	Page 79
IMOVE	Moves pen to a point x and y units from current point.	Page 79
LABEL	Prints contents of the ALPHA register.	Page 92
LDIR	Sets angle of rotation for printing labels.	Page 95
LIMIT	Sets graphic limits in millimeters.	Page 69
LOCATD	Sets plot bounds by digitizing two opposite corners.	Page 106
LOCATE	Sets plot bounds in graphic units.	Page 73
LORG	Sets label origin position.	Page 94
LTYPE	Selects line type.	Page 89
LTYPEO	Selects line type and length of repeat pattern.	Page 90
LXAXIS	Draws and labels x-axis.	Page 102
LYAXIS	Draws and labels y-axis.	Page 103
MOVE	Moves pen to point (x,y).	Page 78
PCLBUF	Clears I/O buffer.	Page 69
PDIR	Rotates axes for incremental and relative plotting.	Page 86
PEN	Selects pen.	Page 88
PENDN	Lowers pen.	Page 88
PENUP	Lifts pen.	Page 88
PINIT	Creates or initializes I/O buffer.	Page 68
PRCL	Recalls an I/O buffer register.	Page 149
RATIO	Calculates x-to-y ratio of current graphic limits.	Page 71
SCALE	Sets user scale.	Page 72
SETGU	Switches module to GU mode.	Page 68
SETUU	Switches module to UU mode.	Page 68
TICLEN	Sets tic lengths.	Page 100
UNCLIP	Resets plot bounds to graphic limits.	Page 74
WHERE	Enters coordinates of last point and current pen status.	Page 106
XAXIS	Draws x-axis.	Page 99
XAXISO	Draws x-axis with tics.	Page 100
YAXIS	Draws y-axis.	Page 99
YAXISO	Draws y-axis with tics.	Page 100

Plot-Option Functions:

IPOINT	Moves or draws to a point x and y units from current point.	Page 81
PLOT	Moves or draws to point (x,y).	Page 81
PLREGX	Moves or draws to series of coordinate points stored in data registers.	Page 83
RPOINT	Moves or draws to a point (x,y) relative to an assumed origin.	Page 82

Utility Plotting Program:

NEWPLOT	Initializes module for generating a plot.	Page 22
PLANOT	Annotates plot according to NEWPLOT and REPLOT parameters.	Page 61
PLINIT	Initializes module for plotting from NEWPLOT and REPLOT parameters.	Page 38
PLTUXY	Generates a function or data plot according to NEWPLOT and REPLOT parameters.	Page 39
REPLOT	Prompts for plot generation or parameter editing.	Page 25
X?	Prompts for next x-coordinate.	Page 41
Y?	Prompts for next y-coordinate.	Page 41

Bar Code Functions:

BC	Plots a row of HP-41 bar code.	Page 127
BCA	Creates bit pattern for Alpha-Replace bar code.	Page 130
BCAA	Creates bit pattern for Alpha-Append bar code.	Page 131
BCCKSM	Computes checksum of bit pattern in ALPHA register.	Page 137
BCO	Plotter Option: Plots bar code row having user-specified leading and trailing bars.	Page 143
	Printer Option: Prints a row of HP-41 bar code on HP 82162A Thermal Printer.	Page 134
BCP	Generates bit pattern for program row.	Page 131
BCREGX	Generates bit pattern from data in a series of storage registers.	Page 136
BCSIZE	Calibrates module to pen width and sets HP or non-HP bar code type.	Page 111
BCX	Creates bit pattern for nonsequenced bar code.	Page 128
BCXS	Creates a bit pattern for sequenced bar code.	Page 129

 y-axis, **27**
 Y minimum, **27**

Addendum

This addendum contains information regarding the *HP 82184A Plotter Module Owner's Manual*, part number 82184-90001, dated September 1982.

Page 69, under `LIMIT`. If, in addition to the plotter, an HP-IL device *other than* an HP 82161A Digital Cassette Drive, an HP 82162A Thermal Printer, an HP 82163 Video Interface, or an HP 82905B Printer is on the loop, the plotter must be selected as the primary device before executing `LIMIT`. (Refer to "Selecting an HP-IL Device" in section 4 of the *HP 82160A HP-IL Module Owner's Manual*.) Otherwise, the HP-41 may display the message **PL:RANGE ERR** when `LIMIT` is executed.

Page 136, under `BCREGX`. When executing `BCREGX`, if there are two or more consecutive specified registers containing zero, the HP-41 may display a **NONEXISTENT** error message. If this occurs, execute `BCREGX` repeatedly until the error message no longer appears in the display. (At most, `BCREGX` will need to be repeated once for each consecutive specified register containing zero.)

Also, when using `BCREGX` with an HP-41C that *does not* have an HP 82170A Quad Memory Module, ensure that the registers you specify exist. Otherwise `BCREGX` may place null bytes in the ALPHA register corresponding to any nonexistent registers which are specified.
